INTRODUCTION

During this workshop I shall give you a description of the technique, go into its purpose, its various uses, the phases of the technique, stressing particularly the theoretical postulates upon which it is based. Then I shall discuss the latest form of administration which is somewhat different from that given in the manual.

I am not going to discuss the post-drawing interrogation session at any particular length in the introductory phase. I shall rely upon the illustrative cases to let you see the P-D-I as we call it (since that's simpler) in action, and let that demonstrate what the P-D-I is for and how it works in actual practice. I think the P-D-I will perhaps have more meaning to you that way than if I simply go over each question individually which you yourselves can do from the manual anyhow.

I am going to discuss very briefly the quantitative standardization and the quantitative scoring. I shall go into the scoring as extensively as you wish and time permits. I rather fancy that you will be more interested in what we now call the "quality of the quantity" than you will be in the quantity as such. The "quality of the quantity" is an entirely new phase which is not discussed at all in the manual. It seems to fill the gap which previously existed between the quantitative scoring and the qualitative analysis. Finally I shall go into the qualitative analysis itself at rather considerable length, perhaps injecting a few points from the marginalia in my manual which may be helpful to you and you can add those to your manuals if you so elect. Then if you like (I will leave this up to you) if time

permits, I think it might be well if I show one case on the black-board, presenting the House, the Tree, and the Person in chalk as the individual himself drew it, showing how I would record the detail sequence, commenting upon what I think were the significant aspects of the recording and then discussing some points of the quantitative and qualitative analysis. Then in subsequent sessions I will go into case records, trying to show you cases that I think will be of interest and in certain instances giving you the Rorschach, too, and perhaps other psychological material. In the last session I am going to summarize completely, much more completely than I shall this morning, almost all of the qualitative aspects that have been identified as having differential value, or are now believed to have such differential value.

PURPOSE OF THE H-T-P

First of all, "What is the purpose of the H-T-P?" The answer to that question might be expressed this way: "To provide psychologists and psychiatrists (and I say psychiatrists advisedly because quite a few, I am happy to say, are beginning to use the technique) with an examining procedure with which to acquire diagnostically and prognostically significant data concerning a subject's total personality and the interaction of that personality with its environment, both specific and general."

"That," you will say, "is a tremendously large order." How nearly we can fill that order at this particular stage of the game I am not too sure, but I think I can show you that we do come somewhere close to doing it. Certainly we can't be hanged for trying, so to speak.

Now for the uses of the H-T-P, and here I should like to interpose a comment: in my opinion the H-T-P should not be used by persons who have not had extensive clinical experience. I should prefer to see it used, if that restriction were actually possible, only by those who have had the benefit of some individual instruction in its interpretation by those who have used it for some period of time. But in the development of a technique that is not always possible. I do think you would say the same thing of the Rorschach, for example.

Now what are the uses of the H-T-P? First of all, we have the matter of differential diagnosis for which the technique was specifically and originally designed. And under that particular heading we have two sub-heads:

- A. To appraise the total personality in an individual examination, (and all else being equal, it is my opinion that the individual examination gives by far the richest data).
- B. To obtain data concerning an individual's progress while under treatment: that is rapidly proving to be one of the most useful aspects of the technique. We have now accumulated enough data over more than ten years time to get some very interesting longitudinal studies.

The second major use is therapeusis. First of all the H-T-P may be used to aid in the establishment of rapport. Then, to go a little deeper, to facilitate free association by simply leaving the drawings on the table and remarking, for example, "Certain people see this as *****. What does this suggest to you?" Then, and I feel that this is the most important aspect under therapeusis, to help an individual to gain insight by slow, very slow and cautious, and increasingly deeper interpretation of his productions, and his comments thereupon.

There are some miscellaneous uses (1) to identify as a group test procedure (as a screening device, for example) the most presumably maladjusted individuals in a given group; (2) to evaluate adjustment prior to entrance into school or beginning specialized training and then again at period intervals thereafter; (3) the H-T-P may be used to appraise adjustment prior to employment, for example, and at intervals thereafter.

DESCRIPTION OF THE H-T-P

"Now", you ask, "what is the H-T-P as a matter of mere mechanics?" The H-T-P is, as it stands now, a two-phased, four-step technique. The non-verbal phase which now constitutes steps one and three is creative, almost completely unstructured; the medium of expression, drawing, is relatively primitive. The verbal phase, steps two and four, is apperceptive. It's really amazing at times to watch a patient treat his drawings in the P-D-I as if he had never seen them before. He acts at times as if you were giving him the TAT. To repeat, the verbal phase is apperceptive, much more formally structured, yet not too much so, as I think you will see from some of the P-D-I responses. In this phase the subject is afforded an opportunity to define, to describe and to interpret (and this is very important) the objects that he has drawn and their respective environments, and to associate concerning them.

Now, let's consider the major theoretical postulates upon which the H-T-P technique is based. I think the essential validity of these postulates has been well demonstrated in clinical usage during nearly 12 years. It is believed that a number of these postulates can be subjected to more or less rigid experimental tests. I certainly hope that before long experimental evidence of their validity can be added to the empirical evidence which has been accumulated.

H-T-P POSTULATES

The first postulate is, "The H-T-P is a projective device". Although its stimuli (remember the only constant stimulus is the printed word at the top of the page, House, Tree, and Person) are objects that are completely familiar they are so completely non-specific that in order to respond to them the subject must project. Here you are not dealing with something which is unfamiliar, you are dealing with something which is basically familiar, even to the very young child. It is rare indeed to find even a young child, for example, who hasn't seen a number of houses and trees, who doesn't know and who isn't emotionally associated with quite a large number of people. He isn't told what house, he is not told what kind of house or what size house he must draw. He is not told the species of tree, the age of the tree, the size of the tree he must draw. He is not told the sex, the age, or the kind of person he must produce. In short, it is left entirely up to him.

Perhaps some of you heard the paper in Denver on the newly produced chromatic TAT. They reported that they had found that the chromatic TAT, containing more easily identifiable material, gave much richer stories, much deeper stories than the achromatic TAT which has less easily recognizable material. To some this seemed to contradict the basic theory underlying the TAT, but I don't think so. It seems to me that in many cases the foreground and background material of the Murray TAT, which is relatively more difficult to identify, served to restrict rather than to enhance projection, for many subjects spent so much time trying to identify and coordinate the foreground and/or background that they gave relatively superficial stories to the main elements of the cards to which they were supposed to project. The fact that the more easily organizable cards tended to give richer stories is in keeping with our experience with the H-T-P, in which, as I have said, the stimuli are completely familiar.

In the Rorschach, of course, the stimuli are more truly unfamiliar though there are many "popular" responses. It appears, then, that to insure projection we must have stimuli that are either completely familiar or almost completely unfamiliar.

Postulate number two is: "In its appraisal of the total personality the H-T-P measures intelligence from several standpoints". (1) Elemental information. These are the specific details which constitute the final finished structure of the House, the Tree, and the Person. (2) The size and spatial relationship of those details (that is, their proportional relationship, their placement within the whole, and so on). And (3) concept formation as evidenced by the organization and the quality of the completed wholes and also (and this must not be overlooked) by the subject's spontaneous and/or induced comments concerning them. You actually have a crude measure of verbal intelligence in the subject's ability to describe, define, and so on, what he has drawn.

Postulate three is: "Each drawn whole, the House, the Tree, and the Person, is to be regarded as a self-portrait as well as the drawing of a specific or (more usually) composite House, Tree or Person, respectively." By self-portrait, we mean more than sheer body projection, per se. In her friendly critique of the H-T-P, Dr. Karen Machover commented, in part: ". . . When a person passes out, it is not the Tree or the House that falls." I cannot quarrel with that, of course, but I have found that symbolically expressed, it may well be the Tree or the House that falls first. Dr. Machover commented further: ". . . Assault is usually expected from the body of a person, and not a House or Tree . . ." Again, I agree, but expected assault upon the body is often expressed symbolically in the drawing of the House or the Tree.

Postulate four: "Each drawing is believed to arouse both conscious, subconscious and unconscious associations." The House seems to arouse associations largely concerning the subject's home and those living in it with him; the Tree, associations concerning his life-role and his ability to derive satisfaction from and in his environment in general (that may be more difficult to accept but I think we can demonstrate by case records the validity of this argument more easily than by going into a lot of verbal discourse); the Person, associations concerning interpersonal relationships, both general and specific. And in each instance (remember this) the past, the present, and the future, psychologically speaking, all or any combination thereof, may be involved and may be emphasized.

The fifth postulate is: "Any emotion exhibited by the subject while drawing or while being questioned concerning his drawings is presumed to represent his emotional reaction to the relationships, situations, needs or presses that he sees or feels are directly or symbolically represented or suggested by one or more of his drawings or some part thereof. "

The sixth postulate: (this gets quite lengthy and is more or less a duplication of what is in the manual, but I think it is very important to consider these theoretical bases). "A subject may indicate that a given detail or detail complex (by detail complex I mean anything beyond one detail and up to and including the completed whole) or the methods of its or their presentation is of special significance to him, in several ways; as a matter of fact in two general ways which I shall discuss separately. " First of all, he may do this positively, by overtly exhibiting emotion immediately before, during or after the drawing of a given detail or detail complex or while discussing it or them in the P-D-I. Now you must not assume that simply because an individual exhibits emotion as he is drawing something, that the emotion is necessarily occasioned by the thing which he is then drawing. It may be an anticipatory reaction or it may be a delayed reaction to something which has been drawn before.

He may indicate significance positively in another way: for example, by presenting the detail or detail complex in sequential order which is deviant from the average. Now we can't say that a person must draw a House, a Tree, or a Person, in any certain way. You are certainly not leaving things unstructured if you make any such requirement as that: the point is that most subjects who are well adjusted do draw Houses in one or two ways so far as the sequence of details is concerned. They may put any number of details in, but the order of production is usually very similar. The same holds true for the Tree, and the same holds true particularly for the Person. So when that order is violated, the examiner immediately becomes suspicious. Note that if the violation of the usual order is not recorded as the drawing is produced, the fact that there has been a deviant sequence may be completely lost in the finished whole. The finished whole may look very good. The inability to produce a whole in the usual conventional, typical sort of way may be the first sign of a beginning breakdown. One of the major differences between the individual session and the group session is that in the group session you can't record detail sequence.

A subject may indicate significance positively also by exhibiting unusual concern over the presentation of a detail. He can do that by erasing excessively, particularly when the erasure is not followed by any improvement. If you get, for instance, a subject who draws a bedroom window; doesn't like it, erases it; redraws it and still doesn't like it; erases and redraws it again and still hasn't improved it, it is reasonable for you to assume that that window means something to him. He can also show this by returning to the detail or the detail complex compulsively -- he may go ahead with his drawing and then come back to a given detail time and time again. I remember one obsessive-compulsive neurotic who drew some few blades of grass in front of her House after she had completed that structure. After she had drawn the trunk of her Tree she turned back to the House and added more grass; then back to the Tree for a branch or two; back to the House with more grass, and so on.

Each of these methods suggests that something is wrong. It is a signpost, nothing more. What we want is more evidence, but if we get enough signposts pointing in the same direction, we probably have pathology. There are a few specific things which definitely are pathological; for example, the omission of the head of a Person, or the omission of the roof of the House (which is almost never seen, incidentally), but most signs are no more than pathoformic. Remember that you are not ascribing significance for the individual, the individual is calling his own signals in this, and he does it in a way of which he, himself, is probably not conscious. This is not the same thing, for instance, as his saying, "I have a lot of trouble with this." In such a case he recognizes inadequacy or conflict and is able to verbalize it. But in the methods I have described before he is doing it in a graphic fashion -- it is he who is doing it, and not you. You will want to interpret it later, that's quite true, but you will also want to allow him to express his own interpretation.

He can indicate significance positively by presenting the detail or the detail complex in deviant fashion. For instance, a person known once to have been intelligent and who draws the arms of his Person as coming from the head may be presumed to be drawing a bizarre figure.

The subject can show significance also by perseveration upon the presentation of the detail. He may, for instance, in finely obsessive fashion draw each individual brick in crayon, outlining each one in black, and then go on and fill in each one in red. He may make

a frank comment, either spontaneous or as the result of questioning on the part of the examiner, concerning the whole or any parts of it. He may state frankly that this or that is significant to him in some way or other.

He may do these things negatively also: he may do that, for example, by presenting a detail or detail complex incompletely. He may, for instance, start to draw two-dimensional branches on a Tree and then fail to close the branches at the end. He may omit altogether one or more essential details (we will go into what is meant by the term essential details as I discuss the quantitative scoring and the quality of the quantity, because this matter of essential details is quite important). He may comment either evasively or refuse to comment at all upon a whole or upon some part which he has drawn, etc.

Postulate number seven, and this, I think, is a very important theoretical aspect which I shall be glad to try to defend if anyone wants to debate the matter at some other time: "In the H-T-P details do not have universal and absolute meaning." The subject's own and at times unique meaning must not be overlooked; he must be given every opportunity to express it. Just before I first reported at the meeting of the State Psychological Society on the H-T-P, Dr. Gilmer came up to me and said, "Buck, don't give me any of this stuff about symbolism. A chimney is a chimney, it is not a penis. I contend that it's a chimney, and that's all there is to it. I am architecturally inclined. I won't have anything else." To which I said, "All right, I'll go along with you, but only if the subject does not show that it is significant". --that is by doing these things which we have just discussed.

Our eighth postulate is: "Interpretation of the H-T-P, both the achromatic and the chromatic, must be made with great circumspection, with great care, and in the light of as complete knowledge as is possible of the subject himself, his past and present environments." That doesn't imply that you can't use the H-T-P if you can't get an accurate and elaborate history, as a matter of fact you can't get a perfectly satisfactory history anyhow (so there isn't any use worrying about that) any more than you can get an examination which will completely satisfy you. You can use the H-T-P in blind analysis without any information about the patient and arrive at a fairly accurate diagnosis in the majority of cases, but if you really want to interpret, and you want to interpret as accurately as you can, for good-

ness sake do so in the light of everything you know about the individual and do so in the light of everything you know about the constellation in which the detail which you are interpreting exists.

That brings us to our ninth postulate: "Interpretation of a given item can be made accurately only after its relationship to the entire configuration has been determined." You may observe that one particular detail in the House makes it look very bad; and yet the rest of the House is nicely drawn. All right then, fine, if you can't find anything else to go along with it, it is probably at the worst pathoformic. You will still want to say, "Well, this may represent something, it may presage a breakdown, somewhere, sometime." You don't want to overlook it, but at the same time you don't want to put too much weight on any one or two isolated items.

Postulate ten: "The subject's reaction to, and use of, color in the chromatic phase furnishes evidence of his tolerance of, control of and reaction to, additional emotion-arousing stimuli, and at a time when he is believed to be peculiarly vulnerable thereto." Now, if there is one thing of which we are reasonably sure about the H-T-P, it is this: The H-T-P is a disturbing technique, since it arouses associations which are often quite unpleasant to the subject. That is, in a sense, validation of the argument that we are getting below the surface of the personality. If we take an individual and we have him draw three things and we question him at considerable length concerning them, and then we hit him with what may be called crude color (because that is what the chromatic phase is) by giving him wax crayons, and we don't permit him to erase, we are definitely putting additional pressure upon him, and at a time when I think we may state that he is more vulnerable.

The eleventh postulate: "Comparison of the quantitative and qualitative analyses of the achromatic and the chromatic sets of drawings provides insight into the degree of permanence of the subject's functioning level of intelligence and the permanence and magnitude of his attitudes, emotions, and so on."

If the subject is but mildly maladjusted, his chromatic H-T-P will ordinarily differ but little from his achromatic H-T-P from a quantitative and a qualitative standpoint (and neither will be more than mildly pathoformic). But if the subject is seriously maladjusted, many of the pathoformic characteristics shown in the achromatic series will be shown - and often exaggerated - in the chromatic series, and other pathoformic signs may appear for the first time.

The twelfth postulate, which was partly contributed by Mr. John Payne, is that one difference between the H-T-P and the Rorschach (and it is very interesting incidentally, to see the way the two techniques bring out points which complement one another) is that the drawing phase of the H-T-P represents personality characteristics as they appear in the effector processes in contrast to the Rorschach which presumably represents characteristics appearing in the perceptual processes. A further argument in that general direction would be that the actual effective acting out, the carrying through of adjustment potentials, is somewhat more vulnerable to in-roads of illness and may, therefore, be the last to recover fully. We do find that occasionally we pick up things a little sooner in the H-T-P than in the Rorschach and sometimes things persist in the H-T-P longer than in the Rorschach. In a recovering patient, for example, signs of pathology may still be pronounced in the H-T-P, 'though the clinical picture itself is clear.

This is just one very mild case in point. John Payne wrote me once that he had given an H-T-P and a Rorschach to an individual who had returned to the Morganton State Hospital (N. C.) originally diagnosed as having had a paranoid psychosis. The patient had been in remission for about 10 or 15 years, I don't remember the exact figure, but it was quite a long time. Mr. Payne said he did his best to find paranoid signs in the patient's Rorschach, but could find none. This patient was not back for hospitalization, he was just back for a checkup and had apparently been doing quite well. The achromatic H-T-P apparently showed nothing. The P-D-I showed no paranoid ideation, but in the chromatic H-T-P there was deviant use of purple. Now almost all that I tell you about color per se in the chromatic H-T-P is to be considered as unproven as yet. But we feel that we have reasonably good evidence for making certain statements: for example, certain colors appear to suggest certain things pretty consistently. But you just can't simply look at any one item and say, "That means so-and-so". One of the things which seems to be the most certain of the theoretical assumptions concerning color is that the use of purple and paranoid characteristics go very closely together. This may have something to do with the Roman purple, I don't know. But we do know that paranoid people tend to use purple and when they use purple they tend to use it deviantly. Incidentally, purple is probably used least of all the colors by well-adjusted individuals.

The thirteenth postulate is that the achromatic-chromatic H-T-P is, in effect, a miniature longitudinal study since it demands that the subject at two different time periods (albeit close together in actual time) perform essentially the same graphic and verbal tasks. In speaking of time we refer here to "psychological" time rather than "chronological" time. Frequently such great changes take place in a subject as a result of his having produced the achromatic drawings and having been questioned about them that it is difficult to believe that a far greater passage of time has not taken place. In other words, the "psychological" time lapse is equivalent to a markedly greater amount of "chronological" time. This is not to imply that basic personality characteristics have changed, but rather that it is now more difficult for the subject to conceal or disguise such characteristics.

So much for the theoretical postulates.

H-T-P TEST MATERIALS

Now I shall go ahead and discuss very briefly the test materials, samples of which were given you. Actually you should have not one drawing form but two, if you are going to use the H-T-P as we now use it. Incidentally, a number of people do not use the formal drawing form for the chromatic phase, they simply take white paper and cut it up, but each page should conform in size to the standard form sheet. Remember that all so-called norms were established using 7 by 8-1/2 sheets. The first page of the drawing form is used for recording such pertinent data as the subject's name, and that sort of thing. The second page has the word House at the top, the third page, the word Tree; the fourth page, the word Person. You should also have two four-page scoring folders, one post-drawing interrogation folder, an eraser, and several lead pencils grade No. 2 (please remember that -- grade No. 2 -- that is quite important.) If you use a lighter grade, you are going to run into certain errors in the interpretation by assuming that your individual is "pencil-shy" so to speak, or "graphite-shy", as you might call it, in that his lines are going to be extremely faint, willy-nilly. And if you give him a very soft lead, you may appear to get pressure signs which actually aren't there. Number 2 appears to be the most flexible grade.

For the chromatic phase you will need a set of Crayola crayons, very cheap, very easily gotten, of eight colors: red, green, yellow, blue, brown, black, purple and orange, respectively (I don't

know whether that sequence has any symbolic significance as far as I am concerned.) Do not limit yourself to eight colors only, however, if your Clinic's budget will permit you to offer a wider selection. The more shades, the better. Of course you will also want a stop watch and a manual. So much for your material. That may sound like a great deal of material, but actually in practice I think you will find that it isn't much.

H-T-P ADMINISTRATION

Now for administration: In Step 1, have several No. 2 pencils with points of varying degrees of sharpness (let the subject have the option of selecting the type of point he wants) lying on the table before the subject, present the subject with a form sheet, fold it so that page 2 only is visible with the word House at the top.

You will notice that the long axis of the first page is the horizontal axis but thereafter the vertical axis is the long axis. I don't know how many of you have read Napoli's monograph on finger painting, but he found that people who were disturbed almost invariably had the horizontal axis of their page the long axis for the first drawing and thereafter tended to turn the paper so that the vertical axis was the longest. By pure chance the page axis for the H-T-P drawing form follows that pattern.

The first thing to watch for is the actual acceptance of the form page by the subject. He may immediately begin to show some negativistic tendencies by either turning it all the way around or turning it sideways. Then say to him, "I want you to draw me as good a House as you can. You can draw any kind you like, you can take as long as you like, you can erase as much as you want, it won't count against you. Just draw as good a House as you can." If he tries to use something else as a drawing aid tell him, no, he mustn't do that; this must be freehand. Tell him not to worry about it, that this is not a test of his ability to draw. You may have to explain that several times, particularly to elderly individuals who protest rather bitterly, "I can't draw, I am not an artist. They didn't teach this when I went to school, etc." Answer such protests with, "That is all right, you will be surprised what you can do." And perhaps he will be. Then after he indicates that he has finished, turn the form page and present page 3 with the word Tree at the top; then, in turn, the fourth page. For the drawing of the Person you may have to amend your instructions to certain relatively illiterate people who simply don't know

what the word "person" means, or for children, for example. Then you will say, "I want you to draw me a man, woman, or child whichever you want." Make no attempt to structure the instructions more than that.

I think the order of the presentation of the stimuli--House, then Tree, then Person--deserves some comment at this particular point. You will notice that we reserve the Person, which probably arouses the most conscious associations, until last in each phase. We want the subject to be less able to defend himself by the time he reaches the Person. If he meets the Person first he may be able to suppress certain material and not produce it in his drawing, whereas he will presumably be less able to censor his production, so to speak, if strong emotionally-tinged associations have already been aroused by the drawing of the House and the Tree. Of course in drawing his Person, the subject has certain body cues which he can use, but at the same time he will be troubled because it is more difficult to produce an aesthetically pleasing Person than a Tree or a House.

But to return to administration: as soon as you've given your last instruction for the House, take your scoring folder (as examiner) and on the first page record the actual detail sequence. The first thing to put down in this is the amount of time elapsing between the completion of instructions and subject's beginning to draw. We call that Initial Latency. You will also record (from the standpoint of time) any pause occurring once the subject has begun to draw, relating that pause to the detail sequence. You will record the total time consumed by the subject for each drawing separately. You will record under House, Tree and Person, by name and by number, the details of the House, the Tree, and the Person, making that breakdown as minute as you can. You will find it valuable when you come to interpret the drawings in the end. It makes a lot of difference.

I have had great difficulty getting some of my interns to do that; they want to cashier on the job, claiming, "I couldn't see. I was busy at the time. I was watching something else. I don't know what crayon he picked up then. You know you can't get these things down." This happened consistently with one intern until he got a subject who practically made his hair stand on end, by producing the most deviant sequence I have ever seen for a Person, drawing first the feet, then the head, then drawing the knees, then legs, and finally connecting all these disjointed segments. The finished product gave no indication of such deviant concept formation. After that, this intern saw some point to detail recording!

You should record all spontaneous comments. You may not be able to do this, of course, verbatim, that is true; but you can at least get the gist of the comment. If you use shorthand, that's all to the good. You will relate those comments to the detail sequence, too. Also record any emotion exhibited by the subject, relating it, also to the detail sequence. That sounds like a big order. The examiner gets quite a workout administering the H-T-P, but the material gleaned is worth it.

Now we come to Step 2. After the subject has completed his achromatic drawings, tell him that he can relax, now, that you are going to ask him a few questions concerning what he has just drawn; that you want to be sure you understand what he has intended, and you would like him to explain what certain of the things may mean to him. Using your post-drawing interrogation folder ask all the questions contained therein. These questions, as you will notice, are purposely spiraled. We start off with rather direct questions and get less and less direct as we go on. We begin with the Person (the last drawn whole) then turn to the Tree and the House in that order; then come back to the Person, back to the House, and so on. This makes it extremely difficult for the individual to remember what he has said for any one whole. For example, suppose that when he first spoke of his Tree, he said the Tree was dead (incidentally, I have never had a dead Tree drawn by a subject who could be regarded as really well adjusted: the dead Tree does not of itself necessarily mean that he is badly mal-adjusted, other things have to come in too, but it is a pathoformic sign), but later in answer to "Is it a healthy Tree?", he said, "I don't know, it may look rather weak." That sort of sequence suggests that the prognosis is fairly good, since he is unwilling to accept everything as completely hopeless. That is just a sample of the sort of thing which you may pull out in the P-D-I.

Now if a subject says when you get to P-6 and ask, "What's he doing?" or "What's she doing there?", "Oh, I don't know, it's just a figure on a piece of paper," that sort of concreteness does not necessarily mean organicity; it might make you suspect it, but you must remember you can get many, many so-called signs of organicity which are not truly organic. You may be getting, instead, the pseudo-organic signs frequently exhibited in some profusion by the functionally disturbed. You say in answer to this, "All right; now don't worry. It may be hard to tell what he is doing here. Maybe you didn't even think of having him do anything, but let's just make up a story about it. Suppose you saw this picture for the first time,

what would it suggest to you? What do you think he might be doing? Where is he doing it?"

If he says, "Oh, he's just standing", continue with, "All right, where is he standing? Inside or outside?" and if he replies, "I don't know, I guess he is inside," you go on and ask, "All right, what room is he in?" and so on.

With some subjects you will find that it is not necessary to ask additional questions. All you need is the slight impact of a question and then you have to quiet the patient down before you can go ahead with other questions. With others you have to pick, and pick, and pick. At times you may get quite a bit of initial resistance, but it usually isn't too hard to overcome it. The P-D-I is intended to help the examiner ascertain the meanings and the connotations the drawings have for the subject, and to make certain that the examiner fully understands the subject's intent because there are certain points in the quantitative scoring system for the full understanding of which you must have a P-D-I. It may be, for example, that you have an individual who draws a Person with an elliptical body that has two-dimensional legs tacked on to an egg-shaped body that the point of juncture necessarily represents the hip. We naively thought so for awhile, then we began to ask people and found out that sometimes the hip joint is just under the arm pit. It is safest to have the individual himself, even in a well-defined drawing, designate where he sees the hip joint as being.

Those of you who heard Dr. Nagler the other night may be interested to know that most of the proportional scores in the H-T-P drawings are actually vertical proportional ratios. Horizontal disparity was found to have very little differential value: it is the vertical ratios which count.

We have now added this to our procedure: after we have given the P-D-I and questioned the subject concerning any possible irrelevant objects which he may have in the foreground or in the background; concerning certain odd pocket placements on his Person's clothes; concerning the position of his Person's hands; concerning what the hands may have in them if the hands are hidden behind the back; concerning what scars on the trunk of the Tree might mean; and so on, we ask him (if he has not already done so spontaneously) to put in each drawing the sun and a ground line. We find that frequently we can get excellent additional qualitative information in this way. We assume from a general theoretical standpoint that the

sun represents the figure of greatest authority or greatest warmth within the environment, and that the placement of the sun in relation to the drawn whole (on the page), and the size disparity between the sun and the drawn whole, can express the subject's view of his relationship to the Person represented by the sun. For example: the subject draws a small Tree with the sun drawn so that it takes up almost a third of the space on the paper with heavy rays coming down from it and focusing on the Tree, and the Tree is drawn as if it were leaning away from the sun: it seems not unreasonable to assume that this subject feels inclined to shy away from domination by someone who makes him feel painfully inadequate.

As for the ground line, the relationship of the drawn whole (that is, the House, the Tree and the Person) to the ground line is the real interest, because the ground line apparently represents reality. If the ground line is spontaneously drawn it appears to be because the patient, himself, feels insecure; feels it necessary to tie his drawing into something substantial on the page. If the ground line (whether produced spontaneously or at the examiner's request) is drawn as anything but horizontal, it appears to have specific implications; for example, if it is drawn going upward to the right of the page, the subject probably feels he has a pretty uphill row to hoe in the future. If it slants downward to the right of the form page, the subject usually expresses a feeling that the future is precarious. If the ground line is presented as an arc with the greatest elevation toward the center of the page, feelings of dependency are to be suspected.

You must always bear in mind, however, that nothing (if one can make such a general statement about anything in the H-T-P) always and necessarily represents any one thing. The most that you can say is that it has strong implications: to be more than a pathoformic sign, it must be supported by other pathoformic signs within the drawings.

Now we come to Step 3: once again you will present your subject with a form sheet with page two only visible, with the word House at the top of the page. This time you will tell the subject that he is to draw as good a House as he can using any or all of the eight crayons before him. We make no attempt to present the eight crayons in any particular order as to color. In this step there should be no pencil and no eraser available, and in this step the subject is not given an opportunity to erase. In giving instructions in this step be very careful not to say, "I want you to draw another House, another Tree, or another Person"--the word another is taboo, for to most subjects it

would imply that he must not duplicate his achromatic drawing. What we want to do is to afford him the widest latitude of choice.

After you have completed the instructions, take another scoring folder and record, just as you did for the achromatic drawings, any initial time latency (and any subsequent latencies), the detail sequence --and in this step it is most important that color be recorded, too--, any emotion exhibited by the subject, etc. The instructions for the drawing of the chromatic Tree and the chromatic Person, in that order of course, are identical with those for the achromatic drawings, except that the subject is told that he may use any or all the crayons at his command.

You will find that subjects vary widely as to their choice and use of color. Some will simply take a black crayon and make a second set of drawings, carefully avoiding any attempt to use color as such. Apparently such use of black serves to enhance by contrast the white space that is thus enclosed, and it seems to indicate not only a tendency to avoid color, but a basic tendency to view the environment with hostility. Other and better adjusted subjects will follow what has come to be regarded as the popular course and will shade easily and quickly and will employ the colors most commonly used for the roof and the chimney of the House, the trunk and branch structure of the Tree, and so on. It is neither wise nor safe, however, to attempt to interpret color usage in the H-T-P in conventional Rorschach fashion. In the H-T-P the initial stimulus comes from within, not from without.

You will find that colors do have meaning. I shall go into some of that as I show Kodachrome slides of patients' chromatic drawings. But colors do not have any absolute and universal meaning. Color appears to become significant only when it is used deviantly, and the more deviantly it is used the more pathoformic the color becomes. Bear in mind, however, that before you can be certain that what appears to be bizarre use of color is actually pathoformic or pathological, you must rule out the presence of color blindness.

After this third step, the chromatic, there is no necessity for giving another full P-D-I unless you have the time and inclination. Neither is there reason why you shouldn't give it if you want to, but by this time the patient is going to be tired and so are you, in all probability, and it may be well to save further questioning for future sessions. You should always question, however, to try to account for any conceptual differences between the two sets of drawings. You may find, for example, as I will show you in one illustrative case,

that the chromatic drawings bear almost no resemblance to the achromatic. That is not too usual! Ordinarily the chromatic is more or less a duplication of the achromatic. And you will want, once again, to have the subject draw the sun and a ground line in each of the chromatic drawings in which he has not already done so spontaneously. Usually your subject will put them in spontaneously in the second set, taking his cue from the examiner's request for them after the first set. It is interesting to see whether he does take the cue or whether, instead, he simply goes ahead once again and draws the House, the Tree and the Person and has to be asked to put the sun and a ground line in.

QUANTITATIVE SCORING

So much for administration. Let us now take just a brief look at the matter of quantitative scoring of the drawings. When the H-T-P was first conceived (and I can't to save my life tell you why I picked on the triad of House, Tree, and Person--that is too far in the past--but they seemed from the first to fit in very nicely and the H-T-P became the H-T-P almost in the very beginning), I worked with it for several years without making any real attempt to quantify, then I decided simply to devise a scoring system similar to that of Dr. Goodenough, but extending it to the House and the Tree. It was a simple matter to construct a point score which actually had a somewhat higher correlation with standard tests of intelligence than the present quantitative scoring system has. I don't think that's an argument against the present quantitative scoring system, however, because I think that about all we were doing at the beginning was duplicating something already well enough done. But as I worked with the point-score system I began to criticize Dr. Goodenough's scoring system, since it made no provision for scoring what was not presented or what was presented but was highly atypically drawn. As I attempted to extend the scope of the scoring system, I began to see why it hadn't been done before. What I wanted to do, for example, was to avoid the possible anomalous scoring which you sometimes get in the drawing of a man, in which you have a fairly high mental age score but the drawn Person has no arms. Obviously qualitatively there is something drastically wrong, yet the quantitative scoring doesn't necessarily reflect it. What I wanted to do was to have a quantitative scoring system to take care of those things which were not drawn and those things which were drawn bizarrely as well as those things which, let us say, were well drawn. Dr. Karen Machover and I have had a good bit of correspondence and we have talked together, too, and we don't

see eye to eye in this matter of the quantitative scoring of drawings. She feels it is a waste of time. I can't agree with that, and I shall try to show you why I don't agree.

In passing, you may be interested to know that there are already several variations of the H-T-P: Perhaps the most commonly used is the H-T-P, which consists of the achromatic H-T-P followed by the directed drawing of a person of the sex opposite to that of the Person drawn in the H-T-P. In short, the clinician combines the H-T-P (achromatic only) with the Machover Draw-A-Person. I'd urge those of you who use this to administer the full P-D-I, however, before asking for the second Person. An ingenious scoring system is that devised by Allan Frankle of Des Moines, who has devised an abbreviated scoring system when he was doing special work at the University of Chicago to appraise the drawings of prospective social workers in graduate school. He has not released this scoring system yet; he feels it needs more validation, but it certainly is an ingenious sort of thing; in a sense it is more qualitative than quantitative, although it is a quantitative score. Other variations are those of Boring and Topper of the V.A. with which you may be familiar. They employ the H-T-P as one of their major screening devices. I think they have done a fine piece of work with it, particularly with the new follow-up that they use. They give the H-T-P as a group test without the P-D-I. Then they present the individual with a mimeographed sheet divided into three small sheets, in a sense, for the House, the Tree and the Person. For the House the upper left gable and the lower right foundation angles are already drawn. There is a vertical one-dimensional line with a small arrowhead with unclosed base suspended above it for the Tree, and the Person is begun with what looks like one of those golf course seats with the curved saddle effect with a line coming straight down and with a dot above--like this . You can imagine what that does to sexually maladjusted subjects. They do all sorts of tricks attempting to get away from it. I think Boring and Topper may extend the use of the H-T-P as a group procedure, because their system is not time consuming to any extent.

Interesting work is being done by Verlin Spencer at San Quentin using water colors as a medium of expression for those with sight, and modeling clay as a medium for those lacking sight. I hope all these men will publish on their work one of these days.

But to come back to quantitative scoring again. The subject's achromatic and chromatic drawings are to be scored quantitatively using the system, which as you know, is based upon the items of de -

tail, proportion, and perspective that were found by their presence or absence to differentiate between subjects on the basis of intelligence. The original standardization population consisted of 140 white adults, ranging in life age (with only one exception) from 16 to 48 years. They were picked because they exhibited no marked personality flaws. We tried to get out of their drawings all those things which differentiated simply on the basis of intelligence. In order to do that we wanted a reasonably well adjusted group. That doesn't mean, of course, that there were no maladjusted in the group itself, but there certainly weren't any who were markedly maladjusted. The number of subjects of each of the seven levels was 20. Placement in a given category was made in accordance with the clinically demonstrated level of intellectual function and not upon the basis of the score or scores earned on any one test or any combination of standard intelligence tests. All subjects except the highest group were administered a great number of tests, however.

The final criterion was the staff's opinion of the clinical picture in the case of those who were of less than average intelligence and it was the opinion of the examiner in the case of those who were above. Those items of detail, proportion or perspective, (we defined a detail as any item which was identifiable as a part; proportion as size relationship; and perspective as spatial relationship) that were found to have differential value were first grossly segregated as either "good" or "flaw," and then assigned a factor symbol. "Flaw" items were those points which appeared in at least 50% or more of the drawings of those of moron or lower intelligence. "Good" items were those which appeared in at least 50% of the drawings of those of borderline intelligence or above. If, for example, the item was given a factor rating of A1 that meant that that particular item was shown by at least 50% of those of borderline intelligence, and by less than 50% of any group of less than borderline intelligence. If an item was given a factor rating of S2 it meant that at least 50% of the people of superior intelligence employed it, but that less than 50% of any group of less than superior intelligence employed it.

The quantitative scoring system, which I am going to discuss very briefly, provides both raw and weighted scores. Four intelligence quotients are derived. You might turn to the second page of your scoring folder to follow this. I think perhaps it will be a little clearer if you do.

First of all, there is the percentage of raw "Good" scores in the total score. Look at your scoring folder: the raw scores for each separate factor rating are summated in the column to the far right marked at the top "grand total raw." The first summation is done horizontally by factor rating and then vertically in that column. The total of the A-scores plus the total of the S-scores equals the total raw "Good" score. Up above that, the total of the D-scores is the total raw "Flaw" score. Now if you will go one column farther to the right you will notice that the total raw scores are convertible into weighted scores by multiplying them by the figures given in the boxes. For instance, if you have two D3 scores, the raw score would be 2, but the weighted score would be 10. If you had say 4 D2's, the D2 weighted score would be 12, and so on. The raw A- and S-scores are multiplied by 1, 2, 3, 4, and 5, respectively.

There are also I. Q. 's for the "Good" weighted score and the "Flaw" weighted score. When we discuss the quality of the quantity in a few minutes, I shall explain why we do these separately.

It is believed that the consistency of these I. Q. scores (remember there are four of them) is diagnostically significant. The H-T-P I. Q. scores are not to be viewed as having the same meaning as the I. Q. scores which you get on the Wechsler-Bellevue, for example. But they are scores. They are actually quotient scores in that they are derived in conventional fashion from the standardization material. The consistency of these scores, that is the consistency of the scores with each other, and particularly the degree with which they conform to I. Q. scores earned by the subject on more formally structured tests of intelligence seems to provide a very good index of the consistency of the subject's level of functioning. Remember we postulated originally that the H-T-P scores were rather vulnerable to inroads of illness. They may go down much faster, for example, than the Wechsler scores. A subject may on the Wechsler seem to be functioning quite well; there may be very little sub-test scatter; but there may be tremendous scatter among the H-T-P scores. The H-T-P I. Q. disparity is a good index then, both of the consistency of the subject's level of intellectual function and also the degree to which that function may be presumed to represent his level of function under optimal circumstances. For example, if the Wechsler I. Q. 's are mildly depressed, but the H-T-P I. Q. 's are sharply depressed, and there is wide scatter among them, we should have a good measure of the effect of the personality disturbance upon the subject's intellectual efficiency.

Look at your "Means Tables": you will notice there are plus and minus signs there. Now the plus sign simply means that the mean was slightly greater than the whole number given. For instance take your imbecile D3 mean: it is marked 3 plus. All that implies is that the imbeciles on an average showed slightly more than three D3 factors, but not enough to justify using the figure 4. If they showed more than three and less than three and a half, it was marked 3 plus. If they showed more than three and a half, but less than four, it was marked 4 minus.

When you consider these mean scores, remember that you are going to find rather wide variances in the means scores of an average well-adjusted subject.

When you take your figures from the grand total raw scores up here and plot them on the means score tables (remember these are raw scores) you can find out some very interesting things. The classification scatter should be of at least three adjacent levels (it is usually three or four). A four-level scatter is not bad at all; in fact, it is a fairly healthy sign. If you had less than a three-classification scatter you would suspect a marked rigidifying of function; conversely a five or six or seven-classification scatter would imply an unhealthy imbalance in the opposite (loosening) direction.

Another ratio to consider is that of the simple total D, A and S raw scores. The subject who has no D-factors in his drawings is just as maladjusted as the person who has a great many, because the tremendous criticality that must pertain for there to be no "Flaw" factors at all is not a good sign necessarily. You will want to have some flexibility and a few D scores, particularly if they are D1's only, means flexibility. Let's take a hypothetical case and say that the subject has, for instance, 12 or 13 D1's, but his A-score and his S-score are in the average to above average range. That is usually an indication of a beginning neurotic breakdown. The D1's are the signs of lessening efficiency. They are only minor flaws, but there are a lot of them. The person's critical ability is lessening somewhat under pressure. He can still produce, as is indicated by his still high "Good" score (A plus S), but something is interfering with efficient function as is shown by the large D1 score.

A large D2 and D3 score usually predicates a psychotic breakdown if the subject is, or recently has been, of at least dull intelligence.

We call the pattern on the means score plotting that makes a V on its side with the high ends (to the right) in the D3 and the A3 level or above, and with the point (to the left) in the D1's -- the neurotic pattern. We call the pattern that has the point of magnitude (so far as Flaw scores are concerned) in the D3 or the D2 and the D3 (to the left) -- the psychotic pattern.

Now please keep these four points in mind when you compare H-T-P-derived I.Q.'s with I.Q.'s derived from formal tests of intelligence, for these things are important. (1) The H-T-P is almost entirely unstructured. The formal intelligence test is almost completely structured (all this in a relative sense). (2) The H-T-P evaluates intelligence as one aspect of the personality constellation and in a setting deliberately designed to be emotion-arousing which would, therefore, presumably penalize function. The formal intelligence test, on the other hand, measures intelligence as nearly in isolation as possible, and in a setting believed to be relatively devoid of emotional arousal. (3) And this holds true not only for H-T-P I.Q.'s but for all H-T-P signs; H-T-P I.Q.'s are to be regarded as signposts only, to be interpreted in the light of all the quantitative and qualitative factors elicited. One of these days when enough people are using the H-T-P to justify it, I should like to give what I would call an advanced H-T-P seminar and go into some of the deep analysis to which the quantitative scores can be subjected. For example, it is interesting to see that a Flaw I.Q. of 60 does not always indicate deficient criticality, but I am not going to confuse you with such things today. The point is simply this: H-T-P scores, raw, weighted, or I.Q. are not to be taken blindly and without consideration. You would not want to accept a D3 factor, for example, as highly pathoformic simply because it was a D3. For instance, if the D3 meant that the drawn Person had no feet, superficially that would seem very bad, but if those feet were simply chopped off by the bottom of the page and the rest of the person was capably presented that would be a sign of feelings of great constriction, and not necessarily an indication of psychosis at all. In other situations this D3 might point to an incipient psychosis. It depends entirely upon its relationship to other parts of the whole.

I repeat: H-T-P I.Q.'s are signposts only. The I.Q.'s of formal intelligence tests, on the contrary, are presumed to stand upon their own merits more or less.

(4) H-T-P I.Q.'s are often highly vulnerable to emotional factors. The I.Q.'s derived from formal tests of intelligence are

relatively more stable. In comparing H-T-P I.Q.'s with those of the Wechsler, for example, you must remember that there is no age-correction factor for the H-T-P I.Q.'s. In a sense H-T-P I.Q.'s may be regarded as E.Q.'s rather than I.Q.'s.

I suppose you all have seen the study of Sloan and Guertin that followed the first section of the H-T-P manual in the Journal of Clinical Psychology, in which Sloan believed he proved that the H-T-P didn't measure intelligence. Sloan was very fair about it. He sent me his manuscript prior to publication and asked for a discussion of it, and I wrote a manuscript which was somewhat longer than his original one. When I sent it back I told him, however, that if he insisted upon his definition of intelligence as that which the Wechsler-Bellevue measured, I didn't care what their conclusions were. I simply couldn't go along with that definition, but that was his definition. I am sure that you will not hold that any one test measures all aspects of intelligence.

But let's return to the quantitative scoring of the H-T-P. Separate scores are derived for details, proportion and perspective. In the normal course of development, details come first. The studies of many others have shown very clearly that when a child first begins to draw the human figure, he starts with the head which he decorates with a pair of eyes and perhaps arms and legs. As he becomes "body conscious" he begins to draw a rudimentary trunk, and so on. As his details become more prolific and more realistic, he becomes conscious of their proportional relationship and he notices that there are certain dimensional differences as well as detail differences; the arms and legs begin to assume a more realistic size relationship to the head, and the head ceases to dominate the figure. While his production of detail increases and proportional size becomes increasingly important, he becomes aware of spatial relationships and the arms and legs are attached to the trunk instead of the head. It follows, then, that a comparison of scores for detail, proportion and perspective can provide, to begin with, additional information concerning the internal consistency of the I.Q. scores. For example, it can indicate what is in the making, so to speak. Suppose you have a per-cent raw G I.Q. of approximately one hundred. On inspection you find an average score for details, you find a moron score for proportion and a superior score for perspective. Yet all this, expressed as an I.Q., would indicate average function. But when you look at this, you say, "Well, that's not average function! What's happening?" This disparity will have given you specific warning that all is not well.

Secondly, this comparison of details, proportion and perspective provides data concerning the basic degree of intellectual maturity. Since details come first, then proportion, then perspective, you would expect that your permanent mental deficient would have a fairly high detail score (and in certain mental deficient you do find a perfectly good average score for details), that the proportion score would be lower, and that the perspective score, representing the highest level of development, would be the lowest -- and that's what you do get. That's your typical permanent mental deficient pattern, beginning with a borderline or dull average detail score, with the proportion score moron or borderline, and the perspective, imbecile or moron. But if your perspective score is really high, even though details and proportion are both low, you have prima facie evidence that once that individual was more intelligent, functioned at a much higher level; probably couldn't have been basically mentally deficient, no matter what he does now.

Thirdly, by this comparison we get information concerning the probable course of a personality disturbance. We have demonstrated that in the normal course of development details are first used, that in turn there develops an appreciation of their proportional and spatial relationships. One of our first assumptions, therefore, was that if someone were becoming disturbed, that fact should be apparent by a drop in the perspective score. That was a good "arm chair" assumption, but unfortunately it did not work out too well. Apparently the most vulnerable of the three scores is the proportion score. So far as a simple anxiety state goes, proportion will go down first and perspective will fluctuate.

With certain schizophrenics the detail score gets shot, and you would expect it to get shot, because your details are actually your reality elements, the basic things: and it is the subject's concept of reality that begins to get fouled up in schizophrenia.

We also analyze separately the scores for the House, the Tree and the Person. Suppose you have, for example, a subject who draws a fine House, an excellent Tree, but an inferior Person. This might offer evidence, and in a sense somewhat objective evidence, that the concept of Person is very disturbing to him. But why is the Person disturbing to him? Is it because of some cosmetic flaw of his own of which he is hypersensitive; or is he, for example, as "body conscious" as certain paranoid schizophrenics who think that everyone is aware of certain facial changes that they believe to be taking place; or is it because social intercourse is unpleasant?

Many patterns are possible. Suppose, for example, that the score for the House is high; that for the Tree low; that for the Person high. Incidentally, it was very difficult to develop many quantitative scoring points for a Tree, because after all a Tree, to be a Tree, needs nothing but a trunk and a branch coming from it -- that's a Tree. It isn't a good Tree, but it is a representation of a Tree of sorts. Consequently the Tree usually has by far the highest score. Even an imbecile may produce a Tree with a superior score. "Now that", you say, "is bad. You should change your quantitative scoring system". Perhaps we should, but if you are going to improve the discrimination of the quantitative scoring for the Tree, you will have to specify the kind of Tree to be drawn and you will immediately thereby reduce the great qualitative value of the Tree. It doesn't seem to be so bad to have one whole that usually scores higher quantitatively than the other two. If you expect the score for the Tree to be highest and it is not, then it has all the more significance. And when it drops well below the others it really has very definite meaning, as I shall demonstrate in some of the cases that I am going to show you in the other sessions. But in this particular instance the pattern of House and Person high, Tree low, suggests an intrapersonal conflict, for the Tree appears to give us an excellent portrait of the subject's subconscious appraisal of the Self in relationship to the environment in general.

QUALITY OF THE QUANTITY

Next we come to the latest development in the appraisal of the H-T-P, which we call the "Quality of the Quantity". We feel that this serves to close the gap between the quantitative and the qualitative systems of appraisal. Now you may well say that there is a very thin line between that which is quantity and that which is quality, but there does seem to be an intermediate area that has aspects of both. For example, the subject's detail score appears to be a quantitative index of his recognition of and his orientation to the elementary, concrete aspects of every day life. His proportion score seems to be an index of his judgment (I use judgment here in a somewhat restricted sense to imply that form of thinking or that form of planning which concerns itself largely with the immediate aspects of things). The proportion score then seems to represent a weighing of the elemental relationship of the details. The perspective score seems to be a measure of the subject's ability to evaluate his environment and his relation to it and those peopling it on a broad basis.

You will remember that I said that the first score to suffer depression by emotional factors was the proportion score. (In appraising relationships you must remember that seldom will the scores for Details, Proportion and Perspective be at the same level -- there is scatter, "normal" scatter, here as well as in the means scores). The proportion score is believed to represent the efficiency level of the function of one's judgment of immediate, everyday problems; it should not be surprising then that the proportion score is frequently the first to be adversely affected, for in periods of great stress it is one's ability to solve immediate problems that is affected.

If you interpret perspective as standing for the ability to solve problems of greater depth, problems of greater time scope, you will apparently be correct. I won't quarrel if you elect to substitute insight for perspective. When the perspective score is depressed we assume that the subject is losing insight. Often the proportion score remains high in the face of a sharp depression of perspective. But that should not be surprising, for subjects may be lacking in insight and yet exhibit fair "every-day" judgment.

We have found it most useful to attempt to account for differences between the Good score and the Flaw score for details, proportion and perspective. In general, the Good score appears to be an index of the subject's ability to function on an acting-out basis. The emphasis is on actual functioning, as one individual to another, as meeting a specific problem, etc. The Flaw score seems to be an index of the subject's ability to appraise critically such relationships (the emphasis here is on aloof inspection and analysis).

I think that can be argued out rather well. The Good score is produced by those items of detail, porportional and spatial relationship that the subject produces in his construction of the three well known things, House, Tree and Person: in short, they represent action on his part. The Flaw scores, on the other hand represent critical failures on the subject's part and seem thus to represent intellection rather than action. There is obviously no sharp dichotomy here, but the emphasis for the Good score appears to be on action, that for the Flaw score on critical appraisal. Support is given this argument by the empirical finding that paranoid individuals usually have a relatively high Flaw I. Q. (hypercriticality) with a somewhat lower Good I. Q. (action efficiency is impaired).

Ordinarily the two scores (Good and Flaw) should probably be within adjacent classification levels. The greater the disparity

between the two scores, the more likely it is that the scores are significant.

Let us suppose, for example, that a subject has a Good score for his Person in the borderline range; but his Flaw score for the Person is in the Superior area. We might interpret this as indicating that he has considerable difficulty interacting easily and efficiently with those with whom he comes in contact (Good score); that he tends to be highly critical of others (Flaw score).

Another subject, for example, might have a Good detail score in the Superior plus range; a Flaw detail score in the dull average area. We might assume (remember that all these assumptions must be tested against the multitude of evidence provided by other points) that this subject was definitely over-concerned about the elements of everyday living (Good score); that his critical appraisal of reality was open to question (Flaw score). Remember these are only signposts. One thing by itself has little meaning. It is the constellation of these things, the relationship of each item to each other item that counts.

In interpreting Good and Flaw scores for details, proportion and perspective we must first see of what factors they are composed (as D3's, D2's or D1's), then we must see how qualitatively important the factors are. For instance, suppose we have someone with a high S-score. On inspection we find all the S-factors are details. This would not connote the same degree of flexibility and maturity of intellect that S-factors in proportion and perspective would imply. Such a person as this might well have a fairly high Fc score on the Rorschach. In short, nothing in the quantitative scoring system can be taken automatically at face value.

It is my belief that for a quantitative scoring system to have real value, it must not be possible to lose sight of the component factors in the whole.

We shall soon give brief consideration to the method of qualitative analysis, so it seems appropriate to reinforce the apparent meanings of the three wholes. The House appears to represent the home, the domestic situation; the Tree, the individual's general role in life. Theoretically, the trunk of the Tree through its size reflects the individual's feeling of basic power. The branch structure, its flexibility, its organization, its size in relation to the trunk, and so on, indicate the subject's view of his satisfaction-seeking resources.

The Person is always, of course, as Machover suggests, a self-portrait. The Person is almost always somebody else, too, and the subject's attitude toward that somebody else must be found out.

QUALITATIVE ANALYSIS

Now we come to the third and final system of appraisal, the qualitative analysis. There was first the quantitative scoring, then the quality of the quantity, and now the qualitative analysis.

Of these systems of appraisal the qualitative analysis is undoubtedly the least objective. It's the most, I think, dependent upon the experience and skill of the examiner. It is often by far the most revealing. You have to be careful not to get so dependent upon it that you abandon the more prosaic quantity and the quality of the quantity which provide you with somewhat more objective signposts that help to keep you from indulging in the flights of phantasy that attract certain Rorschach analysts, who say of their interpretations, "Now this is more refined," when actually it has often become more fantastic. I am not so sure that "refinement" is necessarily a good thing for interpretation. You must be very careful about it.

The standardization group for the qualitative analysis was different from the standardization group for the quantitative system. This time we had 150 white adults, all of whom were definitely maladjusted. The final criterion for subject inclusion (just as it was in the quantitative) was the total clinical picture presented. The subject had to be maladjusted. We wanted to get as many different types of maladjustment as we could. The drawings of the maladjusted subjects were analyzed intensively in an attempt to identify two things: (1) as many as possible of the factors that would serve to differentiate these drawings from the drawings of those who did not have a major personality disorder; (2) factors that might serve to indicate the type of maladjustment exhibited by the subject.

What we had hoped to do when we started out was to assign (as we had to the factors that differentiated as to intelligence) arbitrary symbols to the factors identified as having discriminatory value. These were to be: P-1, P-2, P-3: P-1 to mean a slight deviation from the average, P-2 to mean pathoformic, and P-3 pathological. Unfortunately we couldn't do it, because we found first of all that most of the P-factors had different weight in different configurations. For example, suppose you have two drawings of a

Person, one done by an imbecile, the other by a subject of superior intelligence: in each case the arms have been omitted from the Person. The omission of the arms certainly has very different meaning: the imbecile might well not be expected to draw them in the first place, but the superior subject most assuredly should have put them on, and his failure to do so must have significance.

We also found that not only might a P-factor have different weight in different configurations, but that it might, and often did, have more than one meaning in one and the same configuration.

At the beginning of the course of psychotherapy a patient may state that this means "so and so" to him. Then months later he may say, "I don't know why, but now this means something very different to me than it did before."

It was finally discovered that qualitative appraisal might best be done in the following manner. This is going to be pretty dry, I'm afraid, but I am going to go over the principal points of analysis with their major sub-heads and try to give one illustration of each and then let the case records in the other sessions speak for themselves as we go through them.

In the qualitative analysis, as we did in the quantitative, we begin with an analysis of the details employed by a subject in his drawings of House, Tree, and Person. At this point it may be well to note once again what the essential details are. These "essentials" were at first arbitrarily established: actual practice seems fully to have justified their selection: The House must have at least one door (unless the side of the House only is presented, and that itself is pathoformic); it must have one window, one wall, and a roof and (unless it is identified as a tropical dwelling or something of the sort) it must have its chimney or some means of egress for smoke. Incidentally, if electric heating becomes more and more commonly used in homes, ultimately the chimney may no longer be considered an essential detail for the House. The Tree must have a trunk and at least one branch. The Person must have a head, a trunk, two legs and two arms, unless the position is such that only one of each could be seen (and that's pathoformic), or the absence is accounted for in some way, such as an amputation, for example (I think that also would be regarded as pathoformic). For facial characteristics the Person must have two eyes, a nose, a mouth and two ears, unless once again the position is such that they could not be seen, or the absence is accounted for verbally, as by mutilation, for instance.

The absence of even a single essential detail is to be regarded as serious, and the implications for the presence of pathology are the greater the more essentials are missing and the more wholes there are involved. Less than average, or bare minimal use of essential details, particularly for the House and the Tree, suggests withdrawal and/or conflict in the area represented or symbolized by the detail, or the whole from which it is missing. Excessive use of essential details implies overconcern with whatever may be represented or symbolized by the detail in question.

Non-essential details in general tend to enrich the drawing in which they are used. Examples of non-essentials are: for the House, window curtains; material indicated (whether by careful drawing out or by the use of shading) for the wall, chimney, or the roof; a walkway from the door, etc. For the Tree, there are foliage (again either drawn out in careful detail or implied by shading), a branch system (as in the case of foliage detailed or shaded), bark, etc. And for the Person, there are a neck, hair, clothing, etc.

In general, limited use of non-essential details implies good reality testing; a sensitive, probably rather well-balanced interaction with the environment. Excessive use of such detailing suggests pathoformic overconcern with the environment in general or with the area symbolized or represented by the details used or the details with which they are associated.

Bizarre detailing (the internal organs of a person drawn as visible through clothing and presumed skin, for example) is strongly suggestive of a major maladjustment.

In general, the use of shading to imply the presence of material (roof or wall for the House, bark for the trunk of the Tree, clothing for the Person, for instance) indicates a rather high degree of intelligence and suggests sensitivity rather than anxiety (provided the shading is quickly drawn and easily handled and is not heavy and reinforced).

The first sub-head under details was quantity, the second is relevance. Irrelevancies (that is, objects not immediately associated with the House, the Tree, and the Person, such things, for example, as clouds, mountains, foreground and background objects) are more pathoformic the greater their number and the greater their lack of relationship to the drawn whole.

The third subhead is emphasis. By his positive or negative use of emphasis, the subject indicates himself that the detail or complex of details that he emphasizes has more than ordinary significance for him.

Positive emphasis may be indicated in at least seven ways. I'll name each and give a single illustration for each. First, by over-emphasis on non-essential details (by drawing each item of his Person's clothing most meticulously, for instance); second, by perseverating upon a detail (as by drawing precisely and carefully each two-dimensional leaf on his Tree); third, by returning to a given detail over and over reinforcing its outline (as by drawing over and over the peripheral lines of a branch system); fourth, by deviating from the average sequence of drawing (beginning his Person with the feet, for example); fifth, by excessive erasure, and particularly without subsequent improvement of the detail or details; sixth, by bizarre presentation (as by leaving a House's wall transparent so that the subject's mother could be seen lying in bed sick); and seventh, by the use of what we call traumatic detailing (by producing a Tree trunk bearing a jagged scar, for instance). In connection with this last, you must always remember that the subject will not symbolize a traumatic event in his past unless he himself feels the event to have been psychologically traumatic. You must not assume that because the subject's history contains a record of something that you would have found traumatic, he will have found it traumatic, too. I recall a subject whose history contained an account of no less than three episodes that any psychologist would have considered as most unfortunate. The subject, in this case, drew a Tree whose trunk contained a deep scar. Yet when he was asked to account for its presence, he said nothing about the three episodes in question. Instead he related what I'd ordinarily have regarded as a trivial occurrence in his childhood. But there could be no question that for him it had been a most harrowing experience.

The fourth sub-head is sequence: deviations from the demonstrated average order in which details are produced suggests somewhat precarious personality balance, the existence of which, as I have said before, may well be completely concealed by the finished drawing. Now, just to give you an idea of what can happen: usually a subject starts off by drawing the roof of the House, then he puts in the chimney, then he draws the wall, then the windows and doors, or the doors and the windows in that order, and as a rule he will follow an orderly plan from left to right for drawing the windows and doors, and so on. If, however, he draws first the door and then the left upstairs window,

then the right downstairs window, then the chimney and follows with something else, you are dealing with a person who is at best somewhat confused, so far as his ability to plan and carry out a plan is concerned. If the completed whole gives no indication of the deviant sequence, the subject may be credited with ability to recover from initial confusion, but you must not overlook the original organizational difficulty.

Erotic Manifestations is the fifth sub-head under Details. Let me repeat at this point that the details in the H-T-P are not to be regarded as having universal and fixed symbolic meaning. However, it is not surprising to find subjects who are sexually maladjusted seeing chimneys, tree trunks, fingers, etc., as phalluses, or seeing windows, doors, mouths, etc., as vaginal, rectal, or oral (except in the case of the mouth, of course) substitutes. But the subject who is not sexually maladjusted should have no real difficulty handling details whose sexual connotations are ordinarily more or less hidden, so to speak.

Frank presentation of genitalia on the drawing of the Person is not to be considered as necessarily abnormal if the subject is a young child.

There seems some reason to think that the production of carefully outlined genitalia on the nude Person is more pathoformic than the production of a nude Person in full-face without any identifying sexual characteristics. But neither is it to be regarded as healthy production for an older child or an adult.

The last sub-head under all these headings is consistency - - I won't repeat it for each heading but I will comment upon it here. "Normally" (and whenever I use the word normal it should be presumed to be in quotes) there is a reasonable amount of consistency in the subject's use of details within a given whole and among the disparate wholes. In other words, you may expect that if a subject puts all the essential details in the House he is not going to do so for the Tree and the Person unless there is some definite reason for his not doing it. You will not usually find one whole with a profusion of details, another with almost no details, and the third with a profusion unless there is some very good reason for the absence of the profusion in the second. Things like that don't happen by chance.

Our second main heading is Proportion (that is, size relationship). First we have the proportional relationship of the whole

drawing (the completed House, for example) to the form page. In general, the average whole occupies from one-third to two-thirds of the form page area. Marked size deviation between the drawn wholes is always significant and demands interpretation. If you have a relatively tiny whole, the suggestion is that you have a subject with feelings of inadequacy and perhaps with withdrawal tendencies. The too large whole, the whole that tends to press out against the page's borders, denotes feelings of environmental constriction with -- and this is noteworthy -- with concomitant over-compensatory action or phantasy. He may act out his aggressive tendencies or he may internalize them; the content of the drawing itself may show upon which the emphasis is placed.

The second sub-head is detail to whole (that is, a part to the whole within which that part lies). The greater the size disparity between the part and the whole, the greater the presumed pathoformicity. By disparity we mean deviation from the average size difference detail to whole. The same holds true for detail to detail proportional comparison.

The third major heading is perspective. Just as in the quantitative system we consider details, proportion, and perspective, first. It may relieve you to find out that as you do your quantitative scoring you are already doing part of your qualitative scoring by identifying deviations.

We consider first of all the placement of the whole drawing on the front page. When we started off we had a nice armchair assumption that most people would tend to frame their drawings. There didn't seem to be any reason to expect them to do anything else. We have found, however, (and this may surprise you) that the drawing which is rigidly framed (placed in the exact center of the page) is the drawing of a maladjusted subject. Drawings of well-adjusted subjects are not rigidly framed, neither are the three wholes placed in the same way on their respective form pages. The "normal" midpoint of the three wholes is not the same from drawing to drawing. For example, the base of the Tree is placed on an average, almost an inch higher on the form page than the base of either the House or the Person. The average placement of the whole upon the form page within loose limits is the midpoint of the whole slightly above and to the left of the objective midpoint of the form page.

I might at this point, I suppose, define the rough "dimensions" of the page as we see them. To begin with, we have a "normal"

horizontal midline slightly above that of the page. Placement to the left of the vertical midline tends to emphasize immediate satisfaction of impulses, emotional satisfaction, the historical past and orientation toward the self, and the further to the left of center the greater the emphasis. Placement to the right of that line seems to emphasize a more controlled (delayed) satisfaction of impulses, the intellect as a source of satisfaction ('though on occasion this is really avoidance of emotion), the historical future and orientation toward the environment, and this regardless of handedness, incidentally.

To repeat once again, the greater the degree of placement to the right or the left of center of the form page, usually the greater the emphasis upon one or more of the aspects I have outlined. If we are correct in our interpretation of the meaning of placement of the whole, it shouldn't be surprising that the "normal" midline is not the actual midline of the page but is somewhat to the left of that. I think that almost all so-called average individuals tend to seek immediate satisfaction rather than to delay it; they prefer emotional to intellectual satisfaction; they tend to be more concerned about themselves than about others; the past bothers them more than the future.

NOTE: At this point of the workshop the following question has been asked several times: "May all this be reversed in the drawing of the Person?" (The argument was that in many cases the drawing of the Person mirrors the actual objective relationship of the subject to the drawn Person. That is, the right side of the Person drawn in full-face would represent the left side of the subject drawing it). My answer is that even with subjects of above average or superior intelligence, the drawn Person is often a mirror image. From the standpoint of the interpretation, however, we are concerned with the geographic left of the Person as we view it and not the actual left of the drawn Person. Left and right refer to the left and right of the page itself.

Now when you get a subject who can draw the Person as he actually is; if, for example, you have a subject with a withered left hand and he puts a withered left hand on his Person, that is direct representation. When you get direct representation you may assume that your subject is functioning at a rather high level of efficiency from an intellectual standpoint or he couldn't have done it.

The higher the placement of the whole on the page, the greater the presumed feeling of striving, usually with a concomitant tendency to seek satisfaction in phantasy. Occasionally you may get a

Tree that spills over one or more borders of the page. Such a Tree is most commonly drawn as if it extended beyond the upper limits of the page's border (the upper edge of the page chops off the Tree). In such instances, you will always want to interrogate the subject and ask him how far the Tree goes beyond the page. Not long ago I was told that the top of such a paper chopped Tree would lie 11 inches beyond the page. The subject indicates in this way a tendency to seek satisfaction in phantasy. He can express this more easily in the Tree than in the House or the Person, for a chopped off Tree does not seem as badly mutilated as would a House or Person so depicted.

The lower the placement on the page, the greater usually the feeling of inadequacy, and the tendency toward a depression of mood tone. You may find any of the three wholes "paper based"; that is, with the bottom margin of the page used as if it were both the baseline and the groundline. This almost invariably connotes strong feelings of insecurity and inadequacy. The identification of the presence of a depression of mood, however, depends largely upon the line quality and on the detailing. Subjects who are deeply depressed do not draw many details, they often don't draw complete wholes, and they use very faint lines usually. Low placement on the page by itself is not enough, I think, to justify an assumption of real depression.

Our second sub-head under Perspective is the relationship of the whole drawing to the observer. If, as you look at the House, you get the impression that the House is 'way above you, that you are looking up at it, the presentation is what we call the worm's-eye view. If you get the impression that the drawn whole is below you, that you are above it, you have the bird's eye view. The bird's-eye view usually implies a feeling of superiority in general, and within the home more specifically (at times it will be found to represent a rejection of the "glorification of the home" concept). The worm's-eye view, by contrast, implies a feeling of inferiority, often of rejection from the home (which practically is almost unattainable.)

The whole that is drawn so as to suggest great distance from the viewer, implies unobtainability of the object (and inaccessibility of the self, as a self-portrait).

The House drawn with the sidewall only visible, and the Person drawn in profile in such a fashion that only one arm and/or one leg are visible (the presentation that we call "absolute profile") connote very serious withdrawal and oppositional tendencies. "Absolute

profile" is definitely an unhealthy sign (Mr. Payne feels that it is more pathoformic in the House than in the Person and I'm inclined to agree).

Our third sub-head here is detail to drawn whole placement relationship. Deviations consist: (1) in failure to draw segments in their accepted proportional relationship to the whole; and (2) in the production of transparencies. I have been told that at a Rorschach Workshop a prominent clinician, who was very much interested in drawings at that particular time, made the statement that he felt that if there was as much as one transparency in a drawing the patient must be psychotic. I couldn't possibly go along with that, because I have had neurotic patients who produced as many as 12 transparencies. It depends upon the kind of transparency and where it is. For instance, the ordinary transparency in clothing which, for example, permits the arm to be seen through a sleeve is by no means as serious a reality flaw as the transparency of a House wall which permits objects of furniture to be seen within the House. They are very different things from a qualitative standpoint.

Next we have erotic manifestations under Perspective. That may seem strange, yet actually spatial relationships may reveal certain erotic preoccupations. For example, it can be suggested by the position of the drawn Person, as the female figure drawn with hands overlapping each other and guarding the pelvis.

The sixth sub-head is movement. Of the three wholes the Person is the one most often drawn in movement, of course. Trees come next, and it is not too unusual to have a Tree drawn as if the wind were blowing fiercely and the Tree were bowing before it. Houses are almost never shown in motion. As a general rule you may assume this: The more involuntary, the more violent, and the more unpleasant the movement the greater the presumed pathoformicity.

Finally we have presentation method: this is, the subject's method of depicting details, as, for example, precise and concrete, or abstract by implication. A subject might produce a Tree by drawing two short vertical lines (joining them at the base) then go up a few inches on the page and come back down to his previously drawn trunk, making quick and progressively longer horizontal strokes. Actually, that is quite a satisfactory Tree. We would be justified in assuming that this subject was not over-concerned about details, because he

hasn't bothered to produce them in meticulous, obsessive fashion by drawing out each individual 2-dimensional leaf. The presence of a detail may also be implied: either by position (if the head of a Person is drawn in full profile, for example, we may assume the presence of essential facial details on the hidden side) or by shading (a couple of slanting lines, for instance, would suffice to indicate the presence of glass in the window's frame). The use of shading to imply the presence of details (provided the shading itself is not pathoformic) indicates (1) a fairly high level of intellectual function, since it employs a type of abstraction; and (2) a sensitivity to pressures and forces within the environment (but without undue anxiety). Let me repeat, pathoformic shading is characterized by one or more of the following: (a) excessive consumption of time; excessive force; reinforcement; over-meticulosity or very inferior control in its application.

Details, proportion, and perspective are in a sense the substance, the very skeleton, if you like, of the structuring of a subject's personality through the qualitative analysis of his House, Tree and Person. But other analytical approaches can provide us with valuable clinical data, and the first of these is Time. The first sub-head under Time is total time consumed versus the quality of all the drawings. Average subjects take more than two and not usually more than 30 minutes for each set of House, Tree and Person. Manics and certain schizophrenics may consume less than two minutes for an entire set. It may surprise you to learn that schizophrenics will do that. Consumption of 30 minutes or more for a set is by no means pathoformic if the quality of the drawings is high and thus justifies it. What usually adds to the consumption of time is an immense amount of detailing. If, however, the detailing is not obsessive, it may not be pathoformic. The greater the amount of detailing above average, and particularly irrelevant detailing, the greater the need to structure the environment (and the more insecure the subject presumably is).

Next we have the individual whole versus the quality, which is more important, perhaps, than the total time consumed. Pathoformicity may be presumed if the answer to this question, "Do the details and the way the subject presents them justify the time consumption?", is negative. If the subject produces, for example, a Person and takes a tremendous amount of time in doing so because he erases, redraws, erases, redraws, that is by no means the same thing as if he had taken a lot of time, but had drawn freely and easily and put in a great deal of detail. One of the things that clinicians find rather difficult when they first qualify a set of H-T-P drawings

is to avoid making aesthetic judgments. To an inexperienced eye a given set of drawings may look like something that a subject of defective intelligence would produce and yet the H-T-P I.Q. be in the average range. Remember that the H-T-P quantitative scoring system was deliberately designed to avoid as much as possible any measurement of artistry, as such.

Initial latency is the third sub-head under Time. Most reasonably well-adjusted subjects begin to draw within 30 seconds after the instructions have been given. Any greater consumption of time than that should make one suspicious. What you would probably have would be a subject who was definitely disturbed by the whole which he was asked to produce. He would need time in which to rally his defenses.

For the fourth sub-head we have: intra-whole pause. Any delay of more than five seconds, once a drawing has been begun, suggests conflict with that which has just been drawn or is about to be drawn.

Next comes comment pause. Any spontaneous pause by the subject while he is being interrogated is of course, slightly suspicious, the longer the pause the greater the likelihood of pathoformicity.

The fifth qualitative approach involves an appraisal of line quality. One must be cautious in interpreting line quality. It is rather a difficult thing to do. You have to remember, for example, that the subject who has been engaged in heavy manual labor all his life is not going to be too adept using such a relatively refined tool as a pencil or a crayon, and you mustn't assume that such a subject's crude line structure necessarily represents any organic involvement. First of all we consider line quality from the standpoint of motor control. Any real impairment in motor control suggests the presence of a disturbance, either organic or functional, or both. The identification of the type of disturbance will rest on something beside motor control.

The second sub-head is force. Heavy lines, lines drawn with great force, are usually drawn by organics of (and this you will have to remember, because you will get many so-called organic signs in those who are not organic) those exhibiting extreme nervous tension. An extremely tense subject may draw exactly the same sort of line that some organic subjects use. You will seldom find a psycho-

neurotic employing the classical quavering line of the arteriosclerotic, however. Light, very faint lines are often used by inadequate and/or depressed individuals.

The next sub-head is type of line. Decisive, well-controlled, free-flowing lines tend to imply good adjustment. Broken, indecisive lines, or lines that are continuous only because they have been frequently reinforced are usually pathoformic. Individuals who have had artistic training frequently start off by drawing vague lines which they later erase, but they use them simply as "guide lines". That is not pathoformic. But the line that is broken or hatched initially and becomes continuous later only because of repetitive reinforcement is pathoformic. Remember this, when you are thinking of line quality: the House is ordinarily produced with straight lines only, the Person with more curving than straight lines, and the Tree by a combination of both.

The sixth major analytic point is Criticality: criticism can be verbal or active, or both. Verbal criticism may be restricted to such comments as, "I think this is an unfair test," or "They didn't teach drawing when I went to school". These, strictly speaking, don't constitute real criticism. A subject may, through his comments, reveal the fact that he has real critical ability, but it is only when he can do something about it that it becomes favorable. Erasure without subsequent improvement is not a good sign. Erasure with subsequent worsening is very bad. Persistent erasure and redrawing is pathognomonic of conflict.

The seventh major qualitative point is Attitude. First of all, what is the subject's attitude toward the task as a whole? There are two continua, each begins with "reasonable willingness:" the first goes through "eager acceptance" to "hyper-egotism" (the subject may remark, grandiosely, "I can do anything"); the other ranges down through "indifference", "defeatism" and "abandonism" to "frank rejection"--he just isn't going to have any part of it.

The Person is the most frequently rejected of all the wholes and usually by subjects who find their fellow-men difficult to get along with. As you'd expect, psychopaths reject the Person, they also tend to draw stick men or women for Persons, and they tend to draw caricatures; at times they very savagely degrade the Person drawn.

The eighth major analytic point is that of Drive. Psychomotor increase or decrease automatically arouses suspicion. You will want

particularly to appraise the subject's control of his drive. Does he, for instance, break down under the emotionally-tinged associations that are presumably aroused by the technique, or is he able to handle himself well in spite of them? Progressive psychomotor decrease, House through Person, suggests high fatigability; progressive psychomotor increase, excessive stimulability. One frequently sees subjects who are initially somewhat disturbed but who soon become calm and work efficiently; that is presumably simply test-situational fright and is not pathoformic. If your subject, however, accepts the task without too much protest, produces a fairly good House, shows obvious fatigue on the Tree, and after having laboriously produced the head of his Person abandons the task, you would have to rule out, among other things, a definite depressed state. The drawings of the markedly depressed are characterized by either a marked paucity of details or an inability to complete all three, however scantily, or both.

We come now to a very fruitful phase of the qualitative analysis of the H-T-P--the subject's Comments. Remember that comments may be verbal or written, spontaneous or induced by the examiner.

First of all we inspect the comments made by the subject while he is drawing. Many people say nothing while they are drawing, others say a great deal--children particularly. The absence of spontaneous comments is not pathoformic. You will usually find that the less relevant to the drawing the comment is, often the more revealing it is. The wider the range of topics the subject comments about while actually drawing, the greater the likelihood of pathoformicity.

Unfortunately, we won't have time to discuss the P-D-I here at the length it deserves. While, in general, the drawings themselves contribute most to the development of the personality pattern, in many cases the subject's P-D-I helps greatly to clarify the clinical picture. When I show you some case records, I'll read the entire P-D-I to let you see what it contributes. But there are a few points I'd like to stress now. To begin with, the failure of a subject to reply to a direct question, of course, is pathoformic. So far as relevancy is concerned, if you have highly irrelevant and bizarre replies to direct questioning you are obviously dealing with a seriously maladjusted individual. Hypersubjectivity is also not a healthy sign

The so-called "reality" questions are among the most productive of the P-D-I. For instance, you ask the subject, "As you look at this Tree does it seem to be above you, below you, or on a level with you?" If he says, "It is way above me", whereas objectively it is obviously below the reviewer, he is said to have given an R-minus response (reality minus, that is) and the more R-minus responses you have, the more evidence you have that the subject's reality testing is inadequate.

You will remember that I remarked that the House is usually drawn as upright, the Tree as standing and alive and the Person as upright and alive, that deviations from that are presumably pathoformic. The same thing holds true for comments by the subject concerning movement in the P-D-I. He may say, for example, "The wind is cold; it is blowing; it's blowing hard," which would suggest strong feelings of environmental pressure. The "weather" questions are specifically designed to afford the subject with an opportunity to express symbolically his feelings of pressures, strains and stresses in his environment. If the subject simply describes, for all three wholes, the weather as it is outside at that given moment, don't be surprised, it may simply have no meaning for him, but don't assume, therefore, that the questions are pointless. We must always give him the opportunity to express pressures in this way.

If, for example, when you ask a subject, after he has completed his achromatic drawings to put in the sun, he says, "I can't draw the sun", and when you ask, "Why?", he continues with "Because there are clouds in the sky. You couldn't see it", that pretty well speaks for itself. Clouds in the H-T-P appear to have about the meaning that they have in the Rorschach; actually they may be more significant in the H-T-P, because the clouds are usually drawn out. If the subject draws clouds and draws snow or rain falling, then he certainly feels that the environment in many respects is dismal and oppressive. But we are straying rather far from the P-D-I. The P-D-I questions concerning the "life" of the Tree provide the subject with a further opportunity to project and express symbolically feelings of pressure and to state whether he feels that the source is within or without the Self--or both.

The matters of the identity of the three wholes, the degree of their positive or negative valence for the subject, and the subject's associations with the drawn wholes are all worthy of the time devoted to their consideration.

The newest phase of the H-T-P is the chromatic phase. Presently we analyze the use of color per se under two headings. First of all "choice": the slower, the more difficult and the more indecisive the subject's selection of color, the greater the likelihood of a personality disturbance.

Our second and broader approach is "use", and this is the more important perhaps. We have first of all the "method of expression". How does the subject actually employ his color? Does he use it simply to produce lines (just as he did his pencil) or does he, for example, shade in large areas? Still more important, does he shade some areas and not others? Or does he make a lot of use of what John Payne calls "illumination" color: that is, make specific dots. Does he, in drawing the eyes, make them very blue and prominent by giving them three-dimensionality? Extensive shading, particularly in the foreground and background implies that there is a great deal of anxiety present.

The second sub-head under "Use" is "Amount". First of all what is the number of colors used in each whole? Remember there are always at least 8 colors. As a rule subjects will use fewer colors for the Tree than for the House or the Person. The Tree is usually drawn with green foliage and brown trunk. You must remember when you quantify chromatic drawings that you are going to have a little more shading here than in the achromatic, so you will often find more S's under details in the chromatic than the achromatic. But if you keep in mind that shading is more likely to occur in the chromatic than the achromatic, you will allow for it when you appraise the quality of the quantity.

If the subject uses a single color only, if, for example, he draws a black House, using the crayon just as he would a pencil with no shading whatever you would presume that at best the subject was emotion-shy. Use of black in that fashion serves to accentuate the outlined white space and seems to connote strong oppositional tendencies, the control of which can partly be estimated from the quality of the lines.

In general, children tend to make more prolific and less controlled use of color than adults. This is in keeping with the belief that the emotional response precedes the intellectual in the development of maturity. It is not surprising, therefore, to find regressed subjects using color more freely and with less criticality than non-regressed (with an accompanying lack of interest in form, per se).

Under this sub-head (amount) we are also concerned with the area of a given whole that is shaded. If only a part of a whole is colored by shading you will want to seek some explanation for that.

We are also concerned with the gross area of the form page that is shaded. If as much as three-fourths is colored, the subject may well lack adequate control of his emotional expression. That depends, however, on other factors, too, as does everything else in the H-T-P.

The third major sub-head is "control". Shading that spills over the peripheral lines suggests a tendency to impulsive response to additional stimuli.

The fourth sub-head is "popularity". Two things are to be considered here: first, conformity to popular usage, and second, conformity to reality: they may not be the same thing. You must remember, for example, that in the drawing of the Person it is going to be very difficult to conform to reality completely with the 8-color set of crayons which I have mentioned. It is very difficult, you see, to produce a life-like flesh-color. It can be done by shading with red very lightly, but it is hard to do, and few try it. Most subjects simply use the black crayon (as a pencil) to outline all unclad parts of the Person. This is, of course, a break with reality, but it is not serious because it is a popular method of presentation.

You will be interested to know that Dr. V. J. Bieliauskas, Chairman of the Department of Psychology, Xavier University, Cincinnati, Ohio, will soon publish an article giving a list of the popular color responses in the chromatic H-T-P as indicated by a study done by him and his students.

Next comes "symbolism," and in the chromatic phase, just as in the achromatic, there is no universality of symbols. The more deviantly color is employed, however, the more likely it is to have specific symbolic implication. Certain colors do seem frequently to have a given meaning, but those meanings have by no means as yet received adequate confirmation.

Marked inconsistency from whole to whole, in the use of color, demands careful attempts to learn the "why" therefor.

These ten approaches to qualitative appraisal that I have discussed very briefly are essentially analytical. In the last approach

and in summation, you will want to become synthetic. You will have gone far by now toward identifying the elements of the productions; now you will want to put them all together and see what each whole is as a conceptual production. First of all, you want to examine the content. You can rely on content in the H-T-P to a far greater extent, I think, than you can in the Rorschach. That seems logical, because the subject has produced six, common, well-known objects (two Houses, two Trees, and two Persons) and his concepts of them should represent more basic characteristics than his percepts of ten blots which must in part be influenced by external stimuli.

To recapitulate: we postulate that each whole is a self-portrait, but in addition, for most subjects the House is a specific dwelling or combination of dwellings (it may, for instance, be home as it is now: it may be home as it was in the past: it may be the home the subject would like to have in the future: usually it is a combination); the Tree is often one or more other persons, as is also the Person. The greater the degree of deviation of the concept from the conventional, the greater the likelihood of pathoformicity, but you must remember that the higher the subject on the intellectual scale the more likely he is to produce unconventional concepts. It is, I think, more difficult to produce an original concept on the H-T-P than on the Rorschach. But you can get, for example, a House which is an Irishman's hut; a wind-blown Tree said to be on a tiny Mediterranean island; and a Person who is a Mexican native taking a siesta against an adobe wall. These are certainly original concepts, but whether they are actually pathoformic or not, depends upon a lot of other things. A frankly bizarre concept would almost invariably be pathological.

In appraising the subject's concepts as wholes we are interested in the number of identities given a single whole. One of my subjects not long ago identified his achromatic Person as six different people and he gave a perfectly logical reason for each of his identities. He had constructed a six-man composite Person. Such a multiplicity of identification was, of itself, pathoformic. In general, if a given whole is restricted to self-portraiture only, or if it represents more than three persons, maladjustment may be presumed.

You will be interested, too, in the valence that the subject's concepts have for him. Has he produced six wholes that he likes (that is, which have happy associations for him) or has he produced one or more wholes with unhappy connotations for him? The more

negative the valence of any of the wholes, and the more wholes that have negative valence, the greater is the likelihood that the subject is maladjusted.

Also to be considered is "organization". How quickly, easily and systematically did the individual construct a whole? The greater the difficulty exhibited, the greater the pathoformicity.

If all the wholes are pathoformic, you must suspect organicity, because in the functional cases you usually find at least one whole which the subject produces without too much trouble. That doesn't mean that a subject with a serious functional disorder can't produce six very bad wholes, because he can, but such an overall inefficiency suggests organicity.

To conclude appraisal of concept we must consider "consistency". Perfect or near-perfect consistency for the six drawings (three pencil and three crayon) is as pathoformic as striking inconsistency. At this point of the Workshop the following questions have been asked:

Questions and Answers

Question 1: What were the criteria for subject inclusion in the standardization groups, the one group well-adjusted and the other group maladjusted?

Answer: The criteria for the presumed well-adjusted subjects were rather numerous, perhaps I should have gone into this at greater length before. We had, first of all, the staff diagnosis where the mentally defective subject was institutionalized. And we had comprehensive individual examinations for employees of the borderline to above-average levels. With the above average and superior college students we had to rely upon the teacher's opinion of the student's adjustment: while this left something to be desired, the teachers were psychologists who had had some clinical experience. In the maladjusted group our information was more extensive. There was a comprehensive description of the ward behavior of all institutionalized patients and staff diagnoses were available. Many of the subjects had been examined with the Rorschach and/or the TAT and most had been given one or more intelligence tests. But, as I said before, the final criterion for inclusion was the clinically demonstrated pattern of behavior. We would like to have had a much larger group in each instance, but that wasn't possible. We felt that the best thing

to do, since our sample had to be relatively small, was to examine each prospective subject as rigorously as possible. The other day as I was looking through the drawings of the so-called well-adjusted subjects, I came across a couple that I am now not so sure were as well-adjusted as I thought then, but it would be surprising if we didn't know more about the H-T-P now than we did a number of years ago.

So far as the measurement of our subject's intelligence went, we deliberately avoided (this may have been good or it may have been bad) using the subject's scores on any intelligence test or combination of tests as a criterion (once again it was the total picture that counted). I wanted to avoid getting a high correlation with any other test of intelligence. If we got a high correlation, we would simply have another measure of the same thing. There would be no point to that.

Question 2. When you selected your two groups you tried to get one group that showed marked maladjustment and another group that didn't; wasn't that the idea? You don't claim that your non-maladjusted group were all well-adjusted, do you?

Answer: That was the general idea. The subjects in the maladjusted group were all maladjusted. There were no two ways about it. They were maladjusted by anybody's standards. Some of them had been institutionalized time and again and some had not. In the other group there was no one who was in any way seriously maladjusted. Some undoubtedly had minor personality flaws, it would be very difficult to find an adult who didn't.

Question 3: May we expect physically handicapped individuals to reflect in their drawings their physical handicaps and/or the psychological correlates of those handicaps?

Answer: It has been my experience that it is rare for a physically handicapped person to express his physical disability directly in his drawings (when he does so, however, it is usually in highly dramatic fashion). It is far more likely that such a subject will express graphically and/or verbally his or her reaction to the handicap in question. Some subjects who are severely handicapped physically are undoubtedly more maladjusted psychologically than many of their non-handicapped peers. There is no reason to think, however, that the form of psychological maladjustment exhibited will be any more uniform than the form of the physical disability. The H-T-P offers a subject many, many opportunities, both graphic and verbal, to ex-

press his psychological self-portrait. You should not be surprised to find that two subjects whose psychological maladjustment is very similar will produce at times very dissimilar H-T-P's; that is, they will make use of quite different items in the H-T-P to express their view of themselves.

Question 4: Aren't you disturbed by the fact that so many of the discrete studies that have been made of the validity of the interpretation of certain of the H-T-P qualitative points of analysis have completely failed to produce statistical evidence to support your contentions?

Answer: I'd be very happy, of course, to have such statistical proof of validity. But in view of the almost completely unstructured character of the technique and the many different ways it offers subjects to express their dominant behavioral characteristics, their paramount attitudes, their emotional responses to pressure, their major needs and presses, etc., etc., it appears highly unlikely that such proof will ever be forthcoming. It is most gratifying, however, to be able to report that empirical proof of validity continues to mount.

Those of you who cannot comfortably employ a technique that lacks formal statistical validation should not attempt to use the H-T-P, any more than you should use the Rorschach, for example.

Question 5. I don't want to belabor the point unduly, but just why do you feel that it is highly unlikely that statistical evidence of validity of the H-T-P qualitative points of analysis of a sort that would satisfy the most critical experimental psychologist will be forthcoming?

Answer: To begin with no qualitative point of analysis has a single, fixed, and permanent meaning. Interpretation depends upon the manner in which a detail or detail complex is presented; the relationship to the detail complex, detail complexes, or the whole in which it is presented; and the patient's own interpretation if he expresses it voluntarily or upon interrogation. Too, in a number of instances, it is the absence of a detail or detail complex rather than its presentation that is revealing. We are, of course, very much interested in what the subject does or does not present; but we are even more interested in how he presents it, and most particularly in why.

No two people are identical, so there is no reason to expect that people, regardless of the level of their adjustment will produce identical H-T-P's.

Perhaps an illustration will help make clearer what I am trying to tell you.

Four subjects might draw a Tree with a lower branch broken off and lying on the ground by the Tree. To each of these subjects the broken branch would have a different symbolic significance.

For Subject A, it would represent the emotional trauma he had experienced at the loss of a sibling when A was a young child. For subject B, it would symbolize the destruction he had once wrought in anger upon a specimen tree that this mother almost worshipped. For subject C, it would represent the loss of an arm. For subject D, it would express the traumatic experience of a broken engagement to marry.

On the other hand, we might encounter a number of subjects who had had at least one of the traumatic experiences described by A, B, C, and D, yet not one of them would draw a Tree with a branch broken off.

To put it another way: details, detail complexes, methods of presentation, etc., in the H-T-P have very different meanings for different subjects. So there is no real reason to expect subjects of similar clinical pictures to produce identical H-T-P drawings. Analyses of their H-T-P productions may produce very similar conclusions, but their H-T-P's will vary in many discrete respects.

Question 6: What is your opinion of blind analysis with the H-T-P?

Answer: Blind analysis simply for the sake of blind analysis seems to me to be nothing but a stunt procedure.

The H-T-P has been used quite successfully a large number of times in blind analysis, but it was not designed for that purpose, and no blind analysis can possibly give as much valuable diagnostic and prognostic material as orthodox analysis, so to speak. I disagree wholeheartedly with any psychologist who holds that all projective material obtained from a subject should be analyzed by someone other than the clinician who obtained it.

Blind analysis of the H-T-P, however, does have one significant and practical use: it can serve to provide us with evidence of the validity of quite a few points of the quantitative and the qualitative systems of analysis.

Question 7: What books, other than the H-T-P Manual, would you recommend for the student of the technique?

Answer: The H-T-P Manual Supplement, Jolles' Catalogue for Qualitative Interpretation, Bieliauskas' latest Bibliography, and most certainly Hammer's The Clinical Application of Projective Drawings.

Before I go into a discussion of the qualitative scoring items from an entirely different point of view (segregating the items this time by wholes rather than by general headings of approach), let me remind you once again that the qualitative system of appraisal and most particularly the interpretation assigned individual scoring items, is the least objective of the approaches to an analysis of a subject's drawings of House, Tree, and Person; it is the most dependent for its skillful and successful usage upon the experience and capability of the clinician, but, and this is indeed a large but, it is often by far the most revealing.

First of all, since they appear to be applicable to each of the wholes, let us consider what we have come to call general dimensions. These dimensions refer (1) to the placement of the whole upon the form page and (2) to quadrants of the form page itself.

If you will look at the blackboard you will notice that I have drawn three form pages (for the benefit of the reader these are reproduced on the following pages) and I have put on them certain of these so-called general dimensions.

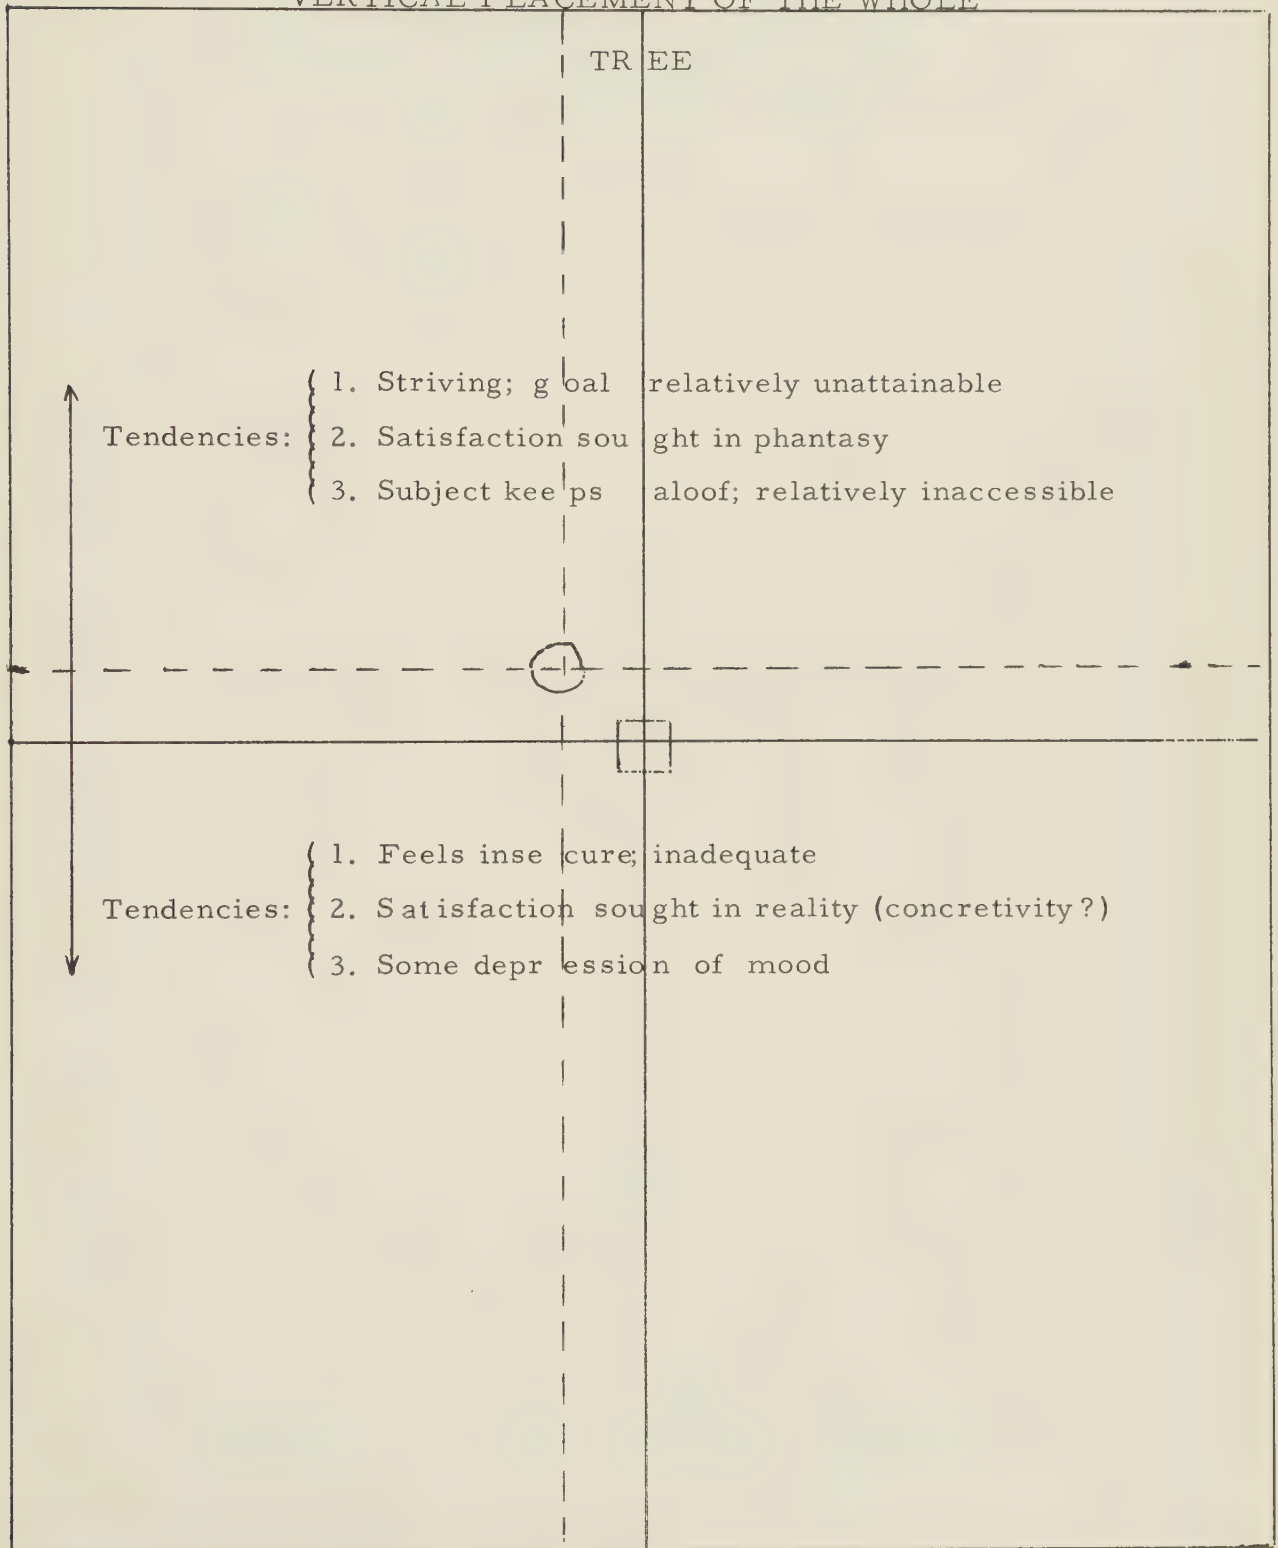

On the first of these pages we are concerned solely with the vertical placement of the whole in relation to the average midpoint of the page.

The higher the midpoint of the drawn whole is above the average midpoint of the page, the greater the implication (1) that the subject feels that he is striving hard, that his goal is relatively unattainable; (2) that the subject tends to seek satisfaction in phantasy rather than in reality; (3) that he tends to keep himself aloof, relatively inaccessible.

 □ = geometric midpoint of the form page

QUADRANTS

From the standpoint of the vertical axis of the drawn whole itself, the baseline seems to represent reality, and the farther one goes upward from that baseline the closer one approaches the phantasy area (the feet of the standing Person, for example, are certainly in immediate contact with reality--the head is the presumed source of phantasy).

The farther below the average midpoint of the page that the midpoint of the whole is located, the greater the likelihood (1) that the subject feels insecure and inadequate, and the greater the likelihood that this feeling is creating within him a depression of mood; (2) that the subject tends to be concrete and to seek satisfaction in reality rather than in phantasy (unless the whole is said by the subject to extend below the page's bottom margin, in which instance, the implication would be that the subject felt himself or herself to be overwhelmingly constricted).

On the next drawing of a form page we are concerned with the horizontal placement of the whole in relation to the average midpoint of the form page. The farther the midpoint of the drawn whole is to the left of the average midpoint of the form page, the greater is the likelihood that the subject tends to behave impulsively, to seek immediate, frank, and emotional satisfaction of his needs and drives. From a temporal standpoint he will be largely concerned with the past; he will be primarily and very largely concerned about himself. Conversely, the farther the midpoint of the whole is to the right of the average page midpoint, the more likely is the subject to exhibit stable, controlled behavior, to be willing to delay satisfaction of needs and drives, to prefer intellectual satisfactions to more emotional ones. He will be concerned about the future from a temporal standpoint; and he will be definitely concerned about those who share his environment with him and their opinion of him.

Just as the placement of the whole itself to left or right of the average midpoint has such implications, so, though to a lesser degree, does emphasis on items within the whole which are to the left or right of the midpoint of the whole itself -- particularly in the Tree.

There is some reason, too, to believe that placement to the left connotes an emphasis on the more feminine characteristics of the personality and that conversely, placement to the right of center suggests an emphasis of the more masculine aspects of the personality, but this is a dubious point.

For those of you who subscribe to the theory of the Persona and the Anima, the general dimensions should have useful implications.

You will realize, of course, that interpretation of vertical placement must be modified in accordance with horizontal placement, and vice versa.

From the standpoint of quadrants (our third drawing) two things stand out: the upper left quadrant (particularly its extreme upper left corner) is known as "the quadrant of regression". Deteriorated psychotics most frequently place their wholes in this quadrant. This quadrant, it must be remembered, is frequently the quadrant of choice of individuals who have never attained any high degree of conceptual maturity (and in such cases it might be called the "quadrant of never was"). In the drawings of older children placement in the upper left quadrant implies a lag in concept maturation.

The lower right quadrant is known as "the unusual quadrant"; almost never is a whole placed entirely in that quadrant.

The whole whose midpoint is placed in the geometric center of the page (that is, the whole is almost perfectly framed with an absence of either vertical or lateral disparity) is the whole of an individual who is rigid in behavior, usually rather anxious and insecure.

HOUSE

So much for the "general dimensions"; let's now consider the wholes, House, Tree, and Person (in that order) discussing for each the apparent interpretative meaning of items of detail and their proportional and spatial relationships.

First of all the House: you will remember that we said that the following details were essential: a roof, a wall, a door, a window and a chimney, or some very good reason (either verbal or positional) to account for the absence of any of these details.

The usual sequence in which details are presented (deviations from which may be regarded as suspicious) are as follows: (1) first the roof and the chimney, then the wall, and then either the door or the window in that order; (2) first a ground line or the base line of

the wall, then the wall, the roof, the chimney, the doors and windows. Vacillant detail sequence is indicative of indecision at best; and the greater the skipping about, so to speak, in presenting details, the presumed greater the disturbance. A definitely pathological detail sequence--one that is believed to be pathognomonic of organicity--is called the "2-Plane" method of presentation. The subject starts out as if he were going to make a conventional 3-dimensional reproduction of a House; ends up by producing an inferior blue-print of the floor plan.

Now to a more specific consideration of the details. We have good empirical reason to think that the roof of the House represents the phantasy area. It is to be noted that imbeciles usually produce Houses whose roof area is a single line only: imbeciles lack the ability to phantasy to any degree, presumably.

If the roof is overly large the assumption in relation to the rest of the House is that the subject devotes much of his time to phantasy, presumably seeks satisfaction therein. If the roof is in poor relationship to the ground floor of the House, it may be presumed that there is poor organization of the total personality. Schizophrenics not infrequently draw Houses which are actually roofs only thus stressing the fact that theirs is largely a world of phantasy.

Emphasis on the eaves of the roof by reinforcement or by extension beyond the walls implies an overly defensive (usually suspicious) attitude.

Roof material is frequently indicated by methods ranging from meticulous outlining of each shingle to a few scattered strokes of the pencil implying the presence of material.

The interpretation of material is based on the method of production, the character of the detailing, the time consumed in its presentation, and the presumed meaning of the area covered. Easily and noncompulsively drawn material appears to indicate merely a mild awareness of surface differentiation and a rather good capacity for well-balanced interaction with the environment; meticulous detailing implies obsessive-compulsive tendencies; deep shading connotes anxiety.

The wall (or walls) of the House seems to depict crudely the Ego of the subject, and its strength or weakness to symbolize the cor -

responding strength or weakness of the Ego. The peripheral boundaries of the personality are represented by the peripheral boundaries of the wall and the roof. If these peripheral (or "containing") lines are over-emphasized, there is believed to be indicated a conscious effort to maintain control. If the peripheral lines are faint and inadequate, there is implied a feeling of impending breakdown, of weak Ego control. If the baseline of the House is the first detail drawn and/or if it is emphasized by reinforcement, well developed feelings of insecurity may be presumed to exist.

Material is drawn less frequently for the walls than for almost any other part of the House, large or small.

Rain spouts and gutters connote a heightened attitude of defensiveness (and usually suspicion), with a concomitant effort to channel off unpleasant stimuli.

From the standpoint of the size of the House as a whole, the very tiny whole is often a regressed concept and, particularly if the detailing is scant, seems to symbolize the lack (or desired lack) of contact with reality and is seen in many cases of acute depression or acute withdrawal from reality. However, if it is well drawn (and has adequate detailing) it probably represents feelings of rather great inadequacy and a conviction that the environment is hostile. On the contrary, if the whole is very large, there may be presumed to exist strong feelings of conflict with the environment to which the subject has reacted by seeking satisfaction in over-compensatory action or phantasy.

If the horizontal dimension of the wall is overemphasized (at the expense of the vertical), the temporal orientation of the subject is thought to be bad because the past and/or the future may be presumed to dominate: the subject may be presumed to be rather vulnerable to environmental pressure since so much of him, figuratively speaking, is available at the reality level for assault and phantasy is not available as a defensive resource. If the vertical dimension is over-emphasized, satisfaction is presumably sought in phantasy, and the subject has less contact with reality than might be desirable.

You will remember seeing in several of the illustrative cases what we call "double perspective" for the House--the presentation in which both endwalls and a sidewall of the House are presented simultaneously. From a developmental standpoint the double perspective

stands between the one-walled House with triangular roof and the so-called superior concept of one endwall and a sidewall. It is not surprising, therefore, to find individuals of dull average to average intelligence employing this form of presentation. It is not to be regarded as pathoformic so long as reasonable proportional relationships are maintained. Two pathoformic proportional deviations have, however, been identified. (1) The moron double perspective and (2) the schizoid double perspective.

Morons frequently employ double perspective, and as a rule they draw very narrow endwalls, produce a broad sidewall. The schizoid double perspective is almost antithetical: the schizoid tend to emphasize the endwalls, to produce a relatively narrow sidewall (at times the endwalls are given material, while the sidewall is left blank).

At times very anxious psychoneurotics will draw a House that gives one the impression that the subject is actually trying to present not only the two endwalls and one sidewall, but the other sidewall as well, which implies a definitely suspicious, anxious attitude toward the environment in general.

If the House is drawn with the wall as a facade (that is, only one wall is shown and little or no impression of depth is given) the suggestion is that the subject tends to don a social mask, so to speak, which may or may not represent his basic tendencies--more usually not.

The dextral and the sinistral differ in their production of a House with end and sidewall. The dextral tends to draw the House with the endwall to the left of the page, the sinistral tends to draw the House with the endwall to the right of the page. A reversal of this customary procedure of presentation is believed to indicate a conscious effort to control, to conform to convention--and the emotional tone may be unpleasant.

When the House is drawn in "absolute profile" (that is the sidewall only of the House is drawn) the fact that it is a sidewall is indicated by the absence of a door, and perhaps accentuated by a porch extending in either direction laterally from the House. Such a presentation suggests a rather acute paranoid reaction, and it apparently has as much significance as the "absolute profile" in the Person.

Recently we have begun to get what we tentatively call the "loss of perspective" sign. An individual who has produced a good endwall and roof will somehow find it impossible to produce adequate representation of depth at the opposite end of the House, and will draw the vertical endline for both roof and wall perpendicular to the baseline of the House. The result is in a sense incongruous: at one end the House shows depth, proper angulation, etc., at the other it looks as if it had been chopped off abruptly. This sign, so far, has appeared only in the drawings of schizoid subjects, and seems to indicate a beginning organizational difficulty -- probably a temporal blocking.

Transparency of the House wall is a grave violation of reality which is seen only in the drawings of low grade mental defectives or of those who are quite seriously disturbed.

To be considered also is the relationship of the drawn whole to the observer (as opposed to the actual placement of the whole on the page in vertical relationship to the page's average midpoint). There is, first of all, what we call "bird's-eye" presentation. The whole may be placed anywhere on the form page, but as one looks at it, he gets the impression that he is looking down upon the House from above. This form of presentation is almost never employed by a subject who feels inferior. It is most frequently seen in the drawings of individuals who feel at least partially grandiose and/or exhibit iconoclastic attitudes and/or behavior.

In sharp contrast is the "worm's-eye" view in which the House is drawn as if it were well above the observer: this form of presentation is usually employed by the subject who feels inadequate, and it seems to express a feeling that the goal is unattainable.

Another aspect of perspective is the impression the observer gets as to the geographic distance between himself and the House. The matter of distance is not entirely based upon the size of the drawn whole: for example, foreground objects may give the impression of considerable distance. The subject who draws his House as far away expresses the feeling that he, himself, is either quite isolated or inaccessible or the home situation is beyond his coping with.

If the House is paper-sided (that is, if the House is drawn so that one of the lateral margins of the page serves as a wall of the House), we assume that the subject is quite insecure, and depending upon whether it is the right or the left margin of the page additional deductions may be drawn. Of all the margins of the page the bottom

is the one most commonly made an integral part of the House. "Paper-basing" is frequently seen and is employed by subjects who feel inadequate (and not infrequently somewhat depressed). I don't think I have ever seen a House that was chopped off by the page's top margin. That is seen occasionally with the Tree, but not with the House, or Person.

The groundline (spontaneous or induced), although it is in a sense a detail, should perhaps be considered under perspective, since it serves to structure the placement of the whole upon the page, and at times enhances sharply the impression of distance and/or height or depth. An arc-like groundline seems to connote strong feeling of dependence (usually on the Mother figure) unless the whole is relatively large and well detailed--in which case needs for exhibitionism and/or dominance may be suspected. The groundline that slopes upward toward the right connotes feeling that the future promises to be difficult and much striving will be needed (but the subject is willing to plug along); the groundline that slopes downward to the right, however, seems to imply a more pessimistic view of the future, and indicates a lessening will to struggle. Incidentally, groundlines are drawn more commonly spontaneously for the House and the Tree than for the Person.

The House is usually drawn as upright and intact. Any actual depiction of movement, as the roof flying off, the walls toppling over, etc., must be regarded as pathological and expressive of a collapse of the Ego under the assaults of environmental or interpersonal pressure or both (depending upon the subject's accounting for the collapse of the House).

Now let's go on with the specific details of the House. First of all we have the door. Ordinarily the door is the detail through which direct contact is made with the environment. It is not surprising, therefore, that it has symbolic significance, and, at times, reveals much concerning a subject's accessibility. Emphasis upon the door's facing or upon locks and/or hinges seems to be indicative of a defensive sensitivity. Emphasis upon the knob suggests an overconsciousness of the door's function and/or phallic preoccupation, or both.

The door that is so extremely tiny as to be called miniscule (that is, a very tiny door that looks almost like a little rat hole) portrays feelings of inadequacy and reluctance to make contact. A door larger than miniscule, but still very small, implies a less reluctant contact. A very large door suggests over-dependence upon others.

If the door is placed high above the House's baseline and is not approached by steps, the subject (at best) is somewhat inaccessible. The higher the door is placed above the baseline and the poorer the relationship of the steps (if any) to that door, the more pronounced is the subject's tendency to dictate the terms upon which he will make contact with his environment.

If the door is drawn as open, and it is not usually drawn that way, it is thought to express a strong need to receive warmth from without, or a need to demonstrate accessibility--if the House is occupied. If the House is vacant it connotes a very strong feeling of a lack of Ego defense.

The windows of the House are simply a less direct and less immediate media of interaction with the environment than the door. If there are no panes drawn in the window, we presume that the subject has definite oppositional tendencies, since the subject is in effect saying, "All right I will present something that looks like a window, but I'll be hanged if I will go any further." If there is a multiplicity of window paning, one often gets the impression that to the subject the window is actually barred as if it were a prison window. Emphasis upon window locks implies overdefensiveness. If the windows are decorated with shutters, shades, or curtains, and the shutters, shades, and curtains are not closed or drawn shut, we usually feel that consciously controlled interaction with some anxiety is implied. If all three are shown, however, the subject is probably a bit too defensive. If some windows are shown with shades or curtains, and others are not, and some are shown with panes and some are not, or windows deviate as to size and/or placement, specific post-drawing interrogation is indicated to see just what caused the disparity. To determine what conflict is being symbolized, the examiner should seek to find out what room is behind the window that differs, find out who occupies the room (if it has an actual occupant) and what sort of room it is (whether it has an occupant or not). The attitude of the subject to the room's occupant (as Father) or the room's function (as bathroom) may account clearly and fully for the deviant presentation.

If many windows are drawn, (and without shades, curtains or shutters) we assume that the subject will tend to behave somewhat bluntly and directly (his many windows indicates a ready willingness to make contact, the absence of shades, curtains, etc., implies that he feels no need to mask his feelings). A multiplicity of windows

with shades, etc., on the other hand, implies overconcern about his interaction with his environment.

General emphasis upon windows and doors by reinforcement and without much detailing connotes concern over interaction, but it would arouse suspicion that the concern might well be at least partially based upon an orificial fixation.

Obviously windows may vary in size without pathoformicity. As a rule, the bathroom window is the smallest window in the House (except for the attic). When the bathroom window is the largest window the assumption would be that the bathroom's function is disturbing to the subject and conflicts concerning sexual and/or eliminative functions would be suspected.

When there is size disparity among the windows of the ground floor, it is "normally" the living-room window that is the largest. A living-room window that is small by comparison to the other windows in the ground floor would make one suspect that the subject had a distinct distaste for social intercourse. The windows of the ground floor, since they are nearer to reality, imply more direct contact, are qualitatively of somewhat more importance, and appear to be more frequently omitted or distorted as to size or placement by subjects who are maladjusted.

If the House is drawn so that the placement of windows does not conform from wall to wall so far as floors go, as in the case I demonstrated this morning, a definite organizational and form difficulty is suggested, and that in turn suggests an early schizophrenia.

Windows are occasionally drawn as open which connotes a high degree of accessibility or a lack of Ego defense, depending upon whether or not the House is said to be occupied.

You may be interested in a couple of specific interpretations of specific details. Last year Dr. Fred Brown of New York told me that a female subject of his who was pregnant had great trouble producing the largest window in the ground floor of her House. In the P-D-I he asked her what that particular window was supposed to be. She said that it was a "bay window". It took her a few minutes to realize that it was only natural that her projection of her own body projection had been difficult.

Miss Selma Landisberg, my former very efficient first assistant, examined a young girl who was illegitimately pregnant. The subject experienced great difficulty in putting on a porch which was finally drawn jutting out at a somewhat odd angle from the House toward the right of the page. The interpretation was that she was expressing symbolically her reluctance at accepting a smaller extension (baby) of herself in the future (page's right).

To continue with the item by item breakdown of the details of the House, we must next consider the chimney. We have come to regard the chimney as one of the major details indicative of the subject's sensual maturity and balance.

The omission of the chimney does not seem to represent as serious maladjustment as does overemphasis of the chimney by (1) size enhancement; (2) reinforcement; (3) difficulty in presentation (as by erasure without subsequent improvement); (4) malplacement; (5) bizarre presentation; or any combination thereof.

Material is drawn more frequently for the chimney than any other detail of the House except window panes. It appears that so far as quantitative scoring goes, material for the chimney does not really merit an S1 rating.

Smoke from the chimney has no quantitative value, but it sometimes has very high qualitative value. Whenever it is produced in great profusion the implication is that there is considerable inner tension.

Dr. Holland, a psychiatrist, formerly at the University Hospital and now in private practice in Charlottesville, suggests that where the smoke is produced as a single thin line one may presume the presence of urethral eroticism. You will accept or reject that according to your orientation toward Freudian concepts. Dr. Holland found that a young boy, to whom he periodically administered H-T-P's from the time he was knee-high to a tadpole, first drew smoke as a single line coming from the chimney of his House, then as he grew older produced smoke more and more conventionally.

Where the chimney is overly large, we may presume that there is some overconcern about sexual matters with a need to demonstrate virility, or perhaps with some exhibitionist tendencies.

There is good clinical evidence, however, that the chimney is not necessarily a sexual symbol (in the restricted sense), but instead may be regarded as expressing the subject's general emotional balance. The roof angled chimney, which is the chimney that projects at right angles to the angulated line of a triangular roof, is almost never seen except in the drawings of normal "young children", or older persons who are mentally deficient or markedly regressed.

If the chimney is visible through a transparent wall, one will suspect poorly suppressed exhibitionistic tendencies, or expression of the subject's feeling that his or her phallic preoccupation must be obvious to others. If the chimney itself is transparent, or if the chimney is drawn as if it were flat and had no depth, there appears to be phallic denial which may either represent impotence or castration fear. The chimney that is drawn as fully exposed and is over-emphasized (usually a large chimney coming down to the ground line) suggests phallic worship with exhibitionistic tendencies. The chimney drawn as almost completely hidden by the House implies at best a reluctance to deal with emotion-producing stimuli.

Feeling of environmental pressure can be expressed symbolically by smoke that instead of simply rising straight up from the chimney veers to one side and thus indicates that the wind is blowing. The magnitude of the pressure (the wind) can be expressed by the degree of deviation of the smoke from a direct, or almost direct upward course, and the magnitude of the feeling is frequently revealed by the quantity of the smoke.

If the smoke indicates that the wind is blowing from right to left, we presume a feeling that the subject's view of what the future has in store for him is anything but optimistic. If the wind is shown as blowing from left to right, the intensity of the wind would have to be greater than that from right to left for pathoformicity to be suspected, since left to right is the conventional direction of force. Smoke is seldom drawn as if blowing to both the left and the right. Such a presentation is obviously bizarre and thus far has been used by psychotic subjects only.

It is well to elaborate P-D-I question H-14 by asking if any wind is blowing, for one may thus elicit a response that is obviously pathological: for example: (1) the subject who has drawn smoke in violent motion may say that no wind is blowing; or (2) the subject may state that the wind is blowing in bizarre fashion as, "In all directions at once", or "From upper left to lower right".

Now, let's consider irrelevant details, (walkways, shrubs, trees, clouds, etc.) first as a group, then more specifically. In general, irrelevant details seem to indicate that the subject has a need to structure the environment more completely, which, in turn, connotes feelings of insecurity and inadequacy. The more profuse the irrelevant detailing, the more intense the presumed feeling. In general the better the irrelevant details are organized and the more intimate their relationship to the House, the greater the likelihood that the anxiety, such as it is, is well-channelized and well-controlled.

The more the irrelevant details tend to dwarf the whole, whether by number, by size, or by placement, the greater the presumed pathologic formicity.

Now for a brief consideration of the apparent meaning of certain specific irrelevant details:

(1) Groundline: The spontaneously produced groundline seems to represent a need on the part of the subject to "tie" his House into something more tangible than mere space. Placement and directional implications of the groundline have already been discussed.

(2) Walkway: The walkway that is easily drawn and well proportioned serves to lend reality and depth to the drawing and seems to imply that the individual exercises some control and tact in his contact with others. The walkway that is very long suggests lessened accessibility. The walkway that is very narrow at its junction with the House, and very broad at the end farthest from the House, connotes an attempt to cloak a basic desire to remain aloof with a superficial friendliness.

(3) Shrubs: Shrubs drawn haphazardly around a House or along the walkway leading to a House seem to imply mild anxiety at the reality level, to represent a conscious attempt to keep it channelized and under control. When shrubs are drawn painstakingly and are of varying size, they will occasionally be found, on careful

questioning, to stand for specific persons, and their size and placement relationship to each other and to the House may have profound qualitative implications.

(4) Sun: The sun, for which we always ask if it has not already been drawn spontaneously (and it usually has to be induced for the achromatic House) appears to represent - when it has symbolic significance (and significance is indicated by reinforcement, size or placement deviation, usually detailing such as odd ray distribution, giving the sun a face with expression, etc.) - the figure of greatest authority or greatest emotional valence (positive or negative) in the subject's environment.

(5) Trees: Trees drawn about the house frequently represent persons, and the examiner should do his best to get the subject to identify them. The type and size of the Tree, and particularly its placement in relation to the House can reveal much about the subject's view of the family constellation. Placement, for example, close to the room that the Person says he would like to occupy within the House, or placement in relation to smaller shrubs that he has identified as siblings, can express dependence, hostility, and so on.

(6) Clouds: Clouds appear to represent generalized anxiety as they do in the Rorschach. They are perhaps somewhat more significant when they are produced voluntarily and spontaneously in the H-T-P than they might be in the Rorschach.

(7) Shadows: Shadows are interpreted as representing a conflict situation producing anxiety at the conscious level when the shadow is produced spontaneously and before a sun has been induced, for by so producing a shadow the subject evidences a subconscious recognition of the presence of something which is not shown within the drawing (the sun) - - otherwise there could be no shadow - - and the fact that the shadow is on the ground indicates its existence in reality - - the conscious area.

(8) Mountains: Mountains in the background suggest a defensive attitude and a need for dependence, often maternal dependence.

(9) Flowers: Tulip or daisy-like flowers are occasionally drawn about the House - - usually by schizoid or very young "normal" subjects. Dr. Richard Ledgerwood, in a study of the spontaneous drawings of schizophrenics at the Eastern State Hospital, Williamsburg, Virginia, found that such flowers were very commonly produced.

(10) There are also what we have come to call degrading details: for instance, there may be an out-house drawn beside a House that is otherwise a mansion. Again, a very large garbage can may be drawn on the front porch. Such irrelevant details usually symbolize feelings of aggressive hostility, at times partially internalized.

(11) Occasionally a subject will emphasize the fact that his House has two stories by drawing a horizontal line at the point of the second floor. This has thus far been found to symbolize fixation upon the soma.

To repeat: the less the relationship of the irrelevant details to the House, the more generalized the anxiety is presumed to be; and the more the irrelevant details tend to dwarf the whole either by their profusion, their size or by their placement, the greater the pathoformicity.

We have now considered the House from the major points of view of Details, Proportion, and Perspective. To round out the qualitative analysis we must consider the other qualitative points, the first of which is Time. A House that is drawn in less than one minute, or a House for which more than seven minutes are taken, should be regarded with some suspicion; excessive time, however, is somewhat less likely to be pathoformic than a very brief consumption of time. Remember once again that your question is, "Do the detailing, the method of organization and the method of presentation, justify the time consumption?"

The initial latency should not be more than 10 to 15 seconds. If there is a longer latency than that (that is, the subject waits longer than that after receiving the instructions before beginning to draw), you will begin to wonder what is producing the block (it may be revealed by the subsequent detail sequence).

Anastasi and Foley, in their study of the spontaneous drawings of the abnormal, found that the abnormal had a longer initial latency period than did the normal. But those were spontaneous productions, and Anastasi's and Foley's findings may not apply to the H-T-P despite our confirmatory experience thus far.

An intra-whole pause implies conflict with that which has just been drawn, is being drawn, or is about to be drawn (or that which it symbolizes in each case).

Next we can consider briefly, the matter of Line Quality. For a very rigid subject, the straight lines of the House may present a lesser problem than the curved lines of the Tree or Person; so he may find the House somewhat easier than the other two wholes. Reinforcement of lines for any detail, or combination of details, suggests conflict aroused by the item or that which it symbolizes. Variation in the decisiveness of the lines also helps to bring into sharp relief the so-called "hot spots". Uniformly faint, hesitant lines bespeak a general anxiety, often accompanied by a sharp depression of mood tone.

From the standpoint of Criticism, there is, first of all, verbal criticism. There are two levels: (1) called observational, which consists of such remarks as, "I wasn't taught to draw a House when I went to school". "I don't think this fair; I am no artist", and so on, (2) called critical, which consists of the identification of some specific inadequacy. But in neither case is any attempt made to correct. Real critical ability (which in contrast to the verbal implies the presence of a fair degree of intelligence and, what is more important, an ability to shift) is shown by erasure with some subsequent improvement. Erasure without subsequent improvement suggests definite conflict aroused by the item presented, or that which it symbolizes, provided the subject is not basically mentally defective or grossly deteriorated - - and even then some conflict may be indicated.

Another main qualitative point is Attitude. Reluctance to draw a House, particularly if the Tree and the Person are later accepted easily, may indicate only an initial reluctance to accept a task of this character, or it may represent definite conflict within the home. Rejection of the House is seldom encountered, far less frequently than rejection of the Person, for example.

From the standpoint of comments, particularly spontaneous ones, remember that often the more irrelevant the comment made while the individual is drawing may seem, the more significant the comment is.

A young woman patient of mine, while drawing her House, spoke very bitterly of an experience (obviously traumatic) that she had had while she was in art school. Afterward I learned that she had never before told anyone about this. Apparently it took nothing more than the act of drawing the House to arouse that association. Usually, however, the association is with the whole itself or a part or parts of it.

Schizophrenics will respond much more readily to intimate personal questioning while they are drawing than they will at any other time.

Written comments on the drawing produced spontaneously are always pathoformic: they are not always pathological, but they are always pathoformic.

Spontaneous comments, whether verbal or written, are believed always to have a definite cause, and the examiner must try to identify it.

We now come to the analysis of the very important verbal phase of the H-T-P, the P-D-I (Post-Drawing-Interrogation). First of all we are concerned with what we call the Reality questions. For the House they are (I am using the 1950 revision of the P-D-I form for the questions as to both number and also wording):

H 1. How many stories does that House have?

H 2. What is that House made of?

H 7. As you look at that House, does it seem to be close by or far away?

H 8. As you look at that House, do you get the impression that it is above you, below you, or about on a level with you?

H14. What is the weather like in this picture?

R-minus responses (reality-minus responses, that is) that do not conform to objective reality - - for example, a House obviously has but one-story, but the subject blandly insists that it is a two-story House - - are pathoformic. The more of these questions given R-minus answers by the subject, the poorer would one presume the subject's grasp upon reality to be.

Next we are concerned with the Association questions:

H 3. Is that your own House? - - Whose house is it?

H 4. Whose House were you thinking about while you were drawing?

H 9. What does that House make you think of, or remind you of?

H10. What else?

H15. Whom does that House make you think of?

H17. If this were a person instead of a tree (or a shrub, or a windmill, or any other object not a part of a House itself), who might it be?

It is most important to determine, if possible, what associations are aroused by the drawing of the House, and particularly their valence (positive or negative) and the intensity of the valence.

The Pressure questions constitute the third grouping of questions. They are:

H 5. Would you like to own that House yourself?

H 6. If you did own that House and you could do whatever you liked with it:

(a) Which room would you take for your own?
Why?

(b) Whom would you like to have live in that House with you? Why?

H11. Is that a happy, friendly sort of House?

H12. What is there about it that gives you that impression?

H13. Are most Houses that way?
Why do you think so?

H14. What is the weather like in this picture?

H16. What does that House need most?

We have found it valuable to ask at this point, "has anything ever damaged this House in any way?" If the answer is affirmative, we try, of course, to learn as much as possible about the type, extent, and cause of the damage, and when it occurred.

These questions, responses to which can reveal much concerning the subject's needs and the stresses and strains placed upon him, should always be supplemented by having the subject either draw a floor plan of his House, identifying all rooms by occupant (if any) and function, or, as is more commonly done, by the examiner's drawing a rough sketch of the House and asking the subject to tell what room is behind each door and window in the wall (or walls) that is visible, and also behind those doors and windows in the wall (or walls) that cannot be seen. Without this information, adequate interpretation of size and placement deviations would be impossible.

Multiplicity of identity for the House, particularly with negative valence, is pathoformic.

Our tenth major analytic point, and the latest to be developed, is Color. We approach our appraisal of the subject's use of color from two standpoints:

A. Choice: The slower, the more difficult, and the less decisive the subject's selection of color is, the greater is the likelihood of pathoformicity.

B. Use: The subject's use of the color, or colors, of his choice, is considered from several points of view:

(1) Method of Expression: Does the subject use color as lines only (does he, for example, use the black crayon as if it were a pencil and eschew any attempt at shading)--at best such a subject is certainly emotion-shy. Or does he use color to imply the presence of material by shading, and is his shading the heavy shading of anxiety or does it, by its character (as relatively lightly drawn and easily and freely produced), connote merely a sensitivity--by no means necessarily unhappy sensitivity--to emotional stimuli? Or does he use dots of color (as what Mr. Payne calls "illumination color") making, for example, a blue eye that is actually 3-dimensional?

(2) Amount: (a) Number of colors used for the House: As a rule, a well adjusted subject who is not color-shy will use not less than two or more than four or five colors for his House. The subject who uses seven or eight colors is certainly highly labile at best.

(b) Area of the House shaded: The chimney and the roof--in that order--are the details most frequently shaded with

color. The examiner should always be suspicious if other areas are shaded and these are not. The area shaded becomes the more significant the more heavily it is shaded and/or the more obsessively it is shaded.

(c) Area of the form page shaded: If more than three-fourths of the page is shaded, even though the shading is well controlled, the subject may be assumed to be very emotional. Fore-ground and background (including sky) shading is the more pathoformic the more it dwarfs the whole by size of area shaded or by intensity of color.

(3) Control: Control is evaluated largely on the quality of the lines and the ability of the subject to keep his shading relatively uniform as to quality and largely within the peripheral borders of the area shaded. Control that is good but not meticulous connotes strength.

(4) Popularity: Under this heading we are concerned with conformity to (a) conventional usage; (b) reality: they are not the same thing. From a conventional standpoint the chimney is red; from the standpoint of reality it might also be, for example, yellow, simulating yellow brick or tile. The roof is most commonly drawn as green, red or brown. A psychotic epileptic indicated dramatically his break with reality by drawing each of the eight windows of his House a different color. The use of black only, to draw the House (without shading) is a conventional use and is, therefore, not to be regarded as having the reality-minus quality that must be accorded the House that is all blue or all yellow, for example. Peculiar combinations of black and red are seen in the drawing of some schizophrenics.

(5) Symbolism: As in the achromatic H-T-P, there is no universality of symbolism in the chromatic. We have not, as yet, accumulated enough evidence to justify our stating that a given color has a specific meaning, but empirically we have come to feel that the eight colors used in the chromatic H-T-P appear to have underlying connotations--connotations that seem to be enhanced the more deviantly the color in question is employed by the subject. I'll give you these connotations, but you must remember that you should not accord these any great weight in any constellation.

(a) Red appears to have warm, sensual implications -- it is apparently the color most difficult for the emotionally disturbed to handle.

(b) Green seems to be a color that produces feelings of security, or at least relative freedom from threat. It has also been called the color of balance. Since green appears so prolifically in nature, its use with the House and the Tree is almost equally prolific, and seems usually to have little meaning.

(c) Blue seems to have two implications (1) an emphasis on control (2) an emphasis on protection.

(d) Black, when used for shading, has a definite dysphoric connotation. When it is used to produce simple lines, black seems usually to be little more than a pencil substitute, so to speak.

(e) Brown is the second most frequently used color by those who try largely to avoid color. Shading of brown (when it is not highly conventional, as for the trunk of a tree) implies defensiveness and an immature response to emotional stimuli.

(f) Yellow (often said by subjects to be used in lieu of white) seems to carry with it strong implications of a hostile attitude on the part of the subject. It is most frequently used for drawing the sun. Its conventional use for the House is largely restricted to depicting light within the House.

(g) Orange (seldom used) is apparently an unhappy combination of sensuality and hostility; seems most frequently to imply highly ambivalent attitudes.

(h) Purple, the least used of the colors, oddly enough, has apparently the most consistent implication: the need for power -- it is never used conventionally for the House.

Let me repeat: the more deviantly a color is used, the greater the justification for a suspicion that the meaning of the color may have played a part in its use.

In evaluating the influence of color in the chromatic H-T-P, you must be careful not to overlook the fact that the subject by the time he begins to employ color, may be assumed to be (1) emotionally aroused; (2) at least mildly fatigued.

In summarizing the House, you will want to examine the subject's concept of House as a whole. As the site of what may be pre-

sumed to be the most intimate interpersonal relationships experienced by the subject, the House arouses associations with family and relatives, and the subject's reaction to those relationships will often be expressed in his drawings of the House. As I said during our first session, the House is always to be regarded as a self-portrait. In addition, however, from the standpoint of content, it represents a dwelling or combination of dwellings. Usually the House will be found to be the subject's own home--of the past, present, or the desired future, or some combination thereof.

The crucial point to consider in appraising the House as an entirety is the ability of the subject to organize his details into a related and meaningful whole.

TREE

I'd like to preface my discussion of the Tree by commenting that the Tree appears to be the best subconscious portrait of the Self of the three wholes. This is in part apparently due to the fact that it seems to arouse the least conscious associations, and, therefore, arouses less ego-defensive action on the part of the subject.

From the standpoint of essential details, all that is necessary to make a Tree which is quantitatively correct is a trunk and one branch; that, as I've pointed out before, is one reason why in evaluating the subject's quantitative scores for the Tree you will attach less weight to a high Good score and a low Flaw score than you would for such scores for House and Person. A low Good score and a high Flaw score for the Tree, however, are highly suspicious. In this connection, I am referring to Raw Scores.

The detail sequence is usually: first the trunk, then the branches and the leaves (either shown as two-dimensional or implied by shading); or first the periphery of the branch structure (which is often shaded in later) and then the trunk.

The trunk appears to be an index of the basic strength of the personality. Reinforcement of the peripheral lines of the trunk implies a consciously felt need to maintain integrity. Faint lines imply a feeling of impending breakdown.

Bark, if easily drawn, implies a well-balanced interaction. If the bark is inconsistently drawn or is very heavily drawn, anxiety

is to be suspected. Vine-line vertical lines on the trunk have so far been seen only in the drawings of pre- or early schizophrenic subjects.

If roots are drawn that are talon-like and do not appear to enter the ground, paranoid attitudes are suggested. Over-emphasis upon roots that enter the ground implies a great need to maintain a grasp upon reality, which is itself indicative of insecurity. Roots that are shown as if the ground were transparent are definitely pathoformic--all the more so if the subject has any high degree of intelligence.

Scars on the trunk are believed always to represent experiences in the past which the subject himself feels were traumatic. One can't necessarily take an anamnesis and assume that the events recorded therein, that might ordinarily be considered traumatic, were actually so to the subject. They will be represented symbolically only if the subject himself found them to be scarring to a degree that demands graphic portrayal.

An overly large Tree trunk suggests feelings of environmental constriction with a tendency to react aggressively in actuality or in phantasy (the size and type of the branch structure will help you to identify which).

A tiny trunk implies feelings of basic inadequacy and ineptness. The trunk that has a very broad base, but that becomes very slender only a short distance above the base, implies an early environment that at best was anything but warm and healthfully stimulating. The trunk that is narrower at the base than at some point or points higher up is a strongly pathoformic sign that suggests a striving beyond the subject's strength, with the concomitant implication of a possible collapse of Ego-control.

Now remember that so far as placement on the page goes, the Tree ordinarily has its trunk's base slightly higher on the form page than the base of either the House or the Person. When the trunk obviously extends beyond the form page's top, the definite suggestion is that satisfaction in phantasy is sought and Ego-control is anything but good. The examiner must always find out from the subject how far the subject feels the Tree so drawn extends beyond the page's top edge. He must also ask the subject whether the trunk of a paper-based Tree extends below the page's bottom edge, and if so,

how far below. Such downward extension suggests that the subject may find suppression his most potent mechanism of defense. Inability to complete the Tree within the page's boundaries is of itself pathoformic.

If the subject draws a Tree that has little height, but the width of the trunk gives the impression that it obviously was once a much taller tree, it is important to ascertain from the subject how tall he thinks the Tree once was, because it, too, may have gone beyond the form page, and the fact that it is now, in effect, chopped off short suggests an acutely traumatic episode in the past. The Tree which is paper-based bespeaks feelings of inadequacy and insecurity with perhaps a concomitant depression of mood.

The branches and the branch system of the Tree are believed to represent the subject's resources for seeking satisfaction in his environment. Overemphasis on the branches to the left of the Tree (either by number, or size, or both) suggests a personality imbalance occasioned by a tendency to seek too strongly for immediate, frank, emotional satisfaction. Overemphasis of the branches to the right, on the contrary, suggests imbalance produced by a too strong tendency to avoid or delay emotional satisfaction, to seek satisfaction instead through intellectual effort (and if the subject is of low level intelligence still further conflict is self-evident.) Absolute symmetry of the branch structure implies feelings of ambivalence; an inability to grant dominance to any course of action.

The greater the flexibility of the branch structure, and the better its organization, the better is the presumed ability of the subject to obtain satisfaction from and in his environment, all else being equal.

Branches indicated by partially drawn two-dimensional branches and shading appear to represent the best adjustment. One-dimensional branches are definitely inferior, particularly if they are drawn without any system, and by branch system we mean a branch to branch organization, not simply a Tree made up of branches, all of which join the trunk and none of which is connected with another.

Branches indicated by unshaded implication carry the connotation of oppositional tendencies.

The rarely seen "white shading" suggests schizoid thinking. In such Trees the white space is given an implied solidity by having two-dimensional branches showing through the white space, in effect, at intervals.

Two-dimensional branches that are drawn like clubs or like fingers and with little organization imply strong hostility. Two-dimensional branches that are phallic-like suggest castration fear. One-dimensional or two-dimensional branches that tend to turn in toward the Tree's center, instead of conventionally extending outward as they go upward, imply strong intratensive ruminative tendencies and thus far have been seen only in the Trees of obsessive-compulsives. Branches that are drawn as two-dimensional, that are thick and very short (as if cut off near the trunk) are believed by Dr. Fred Brown to imply suicidal tendencies. Branches which are drawn as if the subject intended them to be two-dimensional, but are not actually "closed" at the distal end, are usually drawn by subjects who have little control over the expression of their drives.

Broken or dead branches are believed to represent traumatic experiences felt as such by the subject.

If a Tree is drawn as if the trunk had once been much taller, but had been cut off, and one-dimensional branches or tiny two-dimensional branches are growing from the stump, the suggestion is that there is a beginning readjustment. There was an involutional patient at the University of Virginia Hospital, for example, who upon admission, drew a Tree that was a large trunk completely devoid of branches. After he had received large doses of Testosterone for several weeks, he drew the same trunk, but this time there were quite a number of one-dimensional branches growing from it.

Leaves serve at least two purposes: 1. cosmetic, and 2. functional. As a cosmetic they decorate and cover the skeleton of the Tree, and from the standpoint of function they serve to make the most immediate and direct contact with the environment.

The Tree that is drawn with leaves dropping therefrom may express a subject's feeling of being psychologically stripped: that is, he feels he is losing his ability to hide his thoughts and feelings (strong guilt feelings may well be present). He may also feel that he is losing his ability to make more refined and delicate adjustments in and to his environment.

Several female subjects have stated that for them falling leaves symbolized their menstrual function.

If two-dimensional leaves are meticulously and painstakingly drawn, obsessive-compulsive characteristics are presumed to be present.

If two-dimensional leaves are relatively too large for the branches from which they grow, the subject is presumed to wish to mask his basic feelings of inadequacy with a cloak of superficial good adjustment.

You should expect to find deciduous Trees drawn more often as leafless in winter than in summer. Drs. Judson and MacCasland of Marcy State Hospital in New York wrote me that they had found that women tended to draw more barren Trees in the winter than in the summer, but this effect was not present for men. They found, as was, I think, to have been expected, that older patients tended to draw barren trees more often than younger patients.

Just as the roof plus the wall or walls equals the skeleton of the House, so the trunk plus the branch or branches or the branch system is the skeleton of the Tree. A very tiny Tree suggests feelings of great inadequacy to cope with the environment. A huge Tree just as a huge House, and particularly the Tree not contained within the page's borders, implies over-compensatory satisfaction-seeking in action or phantasy, or both, connotes, at best, a hypersensitivity.

A Tree composed of a very slender and/or tiny trunk with a large branch structure implies a precarious personality balance because of satisfaction seeking. A small branch structure with a relatively much larger trunk implies a precarious personality balance because of frustration engendered by inability to satisfy strong basic needs.

The key-hole Tree (the Tree that has no line closing the base of its unshaded branch structure and no line closing the base of its trunk) implies strong oppositional tendencies. It is as if the subject had said, "I'll draw as little as I can to make a recognizable Tree".

The so-called "schizophrenic Tree" is a Tree the trunk of which is actually two-one-dimensional trunks since the sidelines of the trunk never meet at top or bottom. It is as pathognomonic of

schizophrenia as any single H-T-P sign can be said to be pathognomonic of anything.

Subjects with advanced organicity often draw a Tree composed of a one-dimensional trunk with tortuous one-dimensional branches that do not form a system.

An arc-like groundline (with the center the point of greatest elevation) implies primarily maternal dependence, with feelings of isolation and helplessness, if the Tree is relatively small and/or inadequately organized; but if the Tree is rugged and large, the primary implication is that the subject has strong needs for dominance and exhibitionism.

Other types of groundlines appear to have the same meaning for the Tree as for the House.

Remember that shading is somewhat more frequently used on the Tree than on either the House or the Person.

The Tree drawn as on the top of a high hill may imply feelings of grandiosity or feelings of isolation and exposure. If the Tree is drawn as part way up the hill, the implication is the subject feels insecure. The Tree that is placed in a depression, as indicated by the ground line presentation, connotes feelings of inadequacy and depression. The Tree that is placed high on the page connotes feelings of over-striving and the felt ability to strive depends upon the size of the Tree itself.

The Tree that is drawn leaning to the left of the page suggests an imbalance of the personality produced by a desire to secure frank, immediate, emotional satisfaction. The Tree that leans to the page's right implies an imbalance of the personality because of a fear of frank emotional expression with a concomitant overemphasis upon intellectual satisfaction. Placement of the Tree to the left or to the right of the page's midpoint has the same respective implications, but suggests that the tendency is more basic.

Absolute framing of the Tree upon the form page implies an unhappy lack of flexibility.

The Tree drawn in profile (as indicated by the subject's reply to the P-D-I question, "If that were a Person instead of a Tree,

which way would the Person be facing? ") has the same apparent meaning as the House Drawn in profile. The Tree said to have its back to the viewer usually symbolizes a subject's feeling of sharp rejection by the individual represented by the Tree.

In passing, it should be noted that pregnant women draw fruit trees more frequently than do non-pregnant women.

Dependent children tend to draw apple Trees, to express feelings of rejection by drawing apples as falling (or already fallen) from the Tree.

Now let's consider certain commonly drawn irrelevant details:

(1) Groundline: A groundline is drawn spontaneously more frequently for the Tree than for either the House or the Person. We have already discussed general and specific implications of the groundline. When the induced groundline is produced in the form of a box that has no relationship to the Tree, the reality testing of the subject is obviously inadequate. Subjects occasionally draw a gaily ornamented Christmas Tree in a stand suggesting the presence of well-developed narcissism.

(2) Birds and animals: Not infrequently a subject will embellish his drawing of a Tree by adding to it one or more birds or animals. Occasionally, on interrogation, the subject can identify the bird or animal as a person of high valence (positive or negative--more usually the latter) for him. But even when identification cannot be secured, interpretation (I shouldn't have to say it must be very cautious) can be based on the characteristics of the bird or animal, or its action in the drawing. The implications of the buzzard hovering over the Tree, or the horse with tail raised about to defecate on the Tree, are obvious. Somewhat more subtle is the drawing of a Tree with a squirrel's head protruding from a hole in the trunk. This was interpreted as symbolizing a feeling that a segment of the personality was unhappily free from control and presumably had within it destructive potentialities. In this particular case it was obsessive guilt.

(3) Persons: When a Person is drawn near the Tree (and this is very rarely done) that person must, it seems, have significance. A severely disturbed subject, whose relationship with his

Father was most unhappy, drew a huge Tree lying prone on the ground with a man (later identified as the Father) standing beside it with axe in hand. Occasionally a human face will be drawn in the branch structure; recognized only later by the subject. Thus far all such faces have had strong negative valence for the subject.

(4) Trees: It is believed always to be pathoformic if a subject produces one or more additional Trees spontaneously. It is not too unusual to have a maladjusted child draw two Trees and identify them, respectively, as Father and Mother.

(5) Sun: The sun seems to have the same meaning in the drawing of the Tree that it has in the drawing of the House, but the subject can express feeling more graphically in the drawing of the Tree. A subject who was very much dominated by his powerful Mother drew a huge sun, the rays from which were focused on the upper left branch structure; branches in that area were markedly smaller than elsewhere in the Tree: this expressed very vividly the emotional trauma that he had suffered at the hands of his Mother. In contrast, need for affection is expressed by branches reaching appealingly toward the sun. The sun drawn as below the Tree is patently a bizarre production.

(6) Clouds and mountains seem to have the same meaning in the drawing of the Tree as in that of the House.

(7) Wind: The impression that a wind is blowing in the picture can be conveyed as graphically by the position of the Tree as by the position of smoke coming from the chimney of the House. The direction in which the wind is blowing, whether indicated by the position of the Tree, the subject's P-D-I comment, or both, has the same implication that it has for the House.

The greater the force of the wind, the greater the presumed pathoformicity.

Since the comments concerning Time, Line Quality, etc., apply to the Tree and the Person as well as the House, I'll not repeat them. The Tree, however, is ordinarily drawn more quickly than either of the other two wholes.

In appraising the subject's responses to the P-D-I for his Tree we have found it convenient to organize them in accordance with the method I described for the House.

Incidentally, you will note that several of the questions concerning the Tree are believed to be double-edged, so to speak: that is they deal with more than a single one of the general areas reality, pressure, and association.

First of all there are the Reality questions:

- T 1. What kind of Tree is that?
- T 3. About how old is that Tree?
- T 4. Is that Tree alive?
- T 9. Is that Tree by itself or is it in a group of Trees?
- T 10. As you look at that Tree, do you get the impression that it is above you, below you, or about on a level with you?
- T 11. What is the weather like in this picture?
- T 12. Is there any wind blowing in this picture?
- T 13. Show me in what direction it is blowing.
- T 17. Is it a healthy Tree?
- T 19. Is it a strong Tree?

Any R-minus answer connotes pathoformicity: R-minus responses in any profusion strongly suggest pathology.

Next we consider the Association questions:

- T 2. Where is that Tree actually located?
- T 6. Which does that Tree look more like to you: a man or a woman?

- T 7. What is there about it that gives you that impression?
- T 15. What does that Tree make you think of or remind you of?
- T 16. What else?
- T 21. Whom does that Tree remind you of? Why?
- T 23. If this were a person instead of a bird (or another Tree, or anything else not a part of the originally drawn Tree) who might it be?

These questions serve, as they did for the House, to give a crude measure of the subject's ability to abstract, as well as to provide the examiner with far more important qualitative information.

A subject's answer to T6 and his support of his choice in response to T7 can provide insight into his psychosexual maturity. Ordinarily fir trees are seen as masculine; deciduous trees as feminine. The Lombardy poplar, however, is usually called masculine. The oak may represent either a rugged male, or a rather dominant, powerful female figure. The pine, called feminine, the maple, called masculine, connote sexual role confusion.

If the subject says that part of the Tree is dead, you will have him identify the part or parts. If the branches are dead, the implication is that he feels a loss of satisfaction-seeking resources. If the trunk is dead, it implies that he feels a loss of control of his satisfaction-seeking. If the roots are dead, the subject feels a loss of his grasp upon reality.

The subject's statements as to what killed the whole Tree or a part or parts, can be most expressive. If the force is said to be external, such as lightning, insects, children swinging on the Tree or climbing the Tree, someone carving his initials on the Tree, and so forth, the subject is rejecting the idea that he might be weak, but whether or not he is using projection as a defense mechanism would depend upon what the anamnesis furnished in the way of evidence.

If the subject attributed the death of the Tree, or one or more of its parts, to some internal cause--- rot, for example -- the response would be all the more pathoformic, since it would imply a

feeling that it was the Self that was at fault. In such instances, incidentally, you should test for the presence of somatic delusions.

The third category we call Pressure questions. They are:

T 3. About how old is that Tree?

T 4. Is that Tree alive?

T 5. A. (If subject says that the Tree is alive)

(a) What is there about the Tree that gives you the impression that it's alive?

(b) Is any part of the Tree dead? What part?

(c) What do you think caused it to die?

(d) How long has it been dead?

B. (If subject says that the Tree is dead)

(a) What do you think caused it to die?

(b) How long has it been dead?

T 8. If that were a Person instead of a Tree, which way would the person be facing?

T 9. Is that Tree by itself, or is it in a group of Trees?

T 11. What is the weather like in this picture?

T 12. Is there any wind blowing in this picture?

T 14. What sort of wind is it?

T 18 & T 20. What is there about it that gives you that impression?

T 22. What does that Tree need most? Why?

Of particular importance to the expression of pressure are the so-called Life questions in this series, T4 and T5.

The statement that the Tree is dead is always pathoformic. I have yet to see a really well-adjusted subject who said his Tree was dead. One must be careful to probe further if the subject says his Tree is dead because it doesn't have leaves or because it is winter: children and adults of limited intelligence often express, in this fashion, a feeling that the Tree is dormant and not actually dead. Whether the subject means dead or dormant can quickly be determined if you ask him if his Tree will come to life again next Spring.

One day, an elderly psychiatrist, who had told me quite bluntly a number of times that he regarded H-T-P interpretation as having about as much validity as crystal ball-gazing, said to me: "Buck, you know quite well that I'd draw a dead pine tree. Now what on earth would that prove?" I did not bother to answer: it seemed scarcely politic (or kind) to remind him that it had not been long since he had complained bitterly of his sexual impotence.

As with the House, you will want to see what identity the subject gives his Tree and particularly the valence of the identity. Multiplicity of identity for the Tree is less likely to occur than for the House, and far less likely in either case than for the Person.

From the standpoint of Color, brown and green are the colors most commonly used for the Tree: brown for the trunk (and branches if they are drawn out) and green for the foliage. A combination of green and black has been found to suggest a schizo-affective reactive pattern.

Shading is used so frequently for bark, foliage, and grass in the chromatic Tree, as to lower its quantitative value.

From the standpoint of Concept, most commonly the Tree is one near the subject's home, it is a Tree of specific type, and it is usually alive. The crucial factor is the ability of the subject to organize his details and their proportional and spatial relationships into a realistic, meaningful whole.

PERSON

The essential details for a Person are a head, two eyes, two ears, a nose and mouth, and a trunk with two arms and two legs, unless an absence can be accounted for either by the Person's position, or verbally, as by saying, "That arm was cut off" -- pathoformicity may be present even then, of course.

The average detail sequence for the Person is usually first the head, then the facial characteristics (the eyes, the nose, the mouth and the ears, in that order); then the neck, the upper trunk, the arms and hands, the lower trunk, the legs and feet.

A delay in the presentation of the facial characteristics implies a desire to delay final identification of the Person as long as possible. A delay in drawing the fingers or hands until last, or almost last, connotes a marked reluctance to make immediate and intimate contact with the environment -- that is at times predicated upon a desire to avoid revealing feelings of inadequacy.

The head is believed to represent the area of intelligence (control) and the area of phantasy. Emphasis on the peripheral lines suggests strong efforts to maintain control in the face of disturbing phantasy (or obsessive or delusional ideation?)

Well-adjusted subjects of superior intelligence not infrequently draw Persons with heads that are disproportionately large. Such oversized heads are also drawn by subjects who are mal-adjusted, and place undue emphasis upon intelligence per se, or place emphasis upon phantasy as a source of satisfaction. The disproportionately small head is often seen in the drawings of obsessive-compulsives. Karen Machover interprets this as expressing a wish to deny the intellectual control which prevents satisfaction of body impulses. I interpret it as the obsessive's expression of a desire to deny the site of painful thoughts and guilt feelings.

Drawing the Person with the back of the head toward the viewer seems to be definitely pathognomonic of paranoid-schizoid withdrawal. Aversion of the head (not just profile presentation, but as if the head were still further turned from the viewer) implies evasion and withdrawal, but not to the pathological degree of the back of the head presentation.

Hair is presumed to be an expression of virility and virility striving (hair on the chest of the nude male seems always so). Adolescent girls tend to over-emphasize and formalize hair. Heavily-shaded hair implies anxiety concerning thinking or phantasy. Long and unshaded hair (as by implication) suggest highly ambivalent phantasy concerning sexual matters. Beards and mustaches are definite masculine symbols, phallic substitutes.

The face itself is regarded as an index of social adjustment. Emphasis upon the face implies a conscious effort to maintain an acceptable social front.

The eyes, as the receptors of visual stimuli, are perhaps the most revealing detail of the facial constellation. The eyes are usually the first facial detail drawn by the young child. If the eyes are drawn as hollow sockets, with no attempt on the part of the subject to indicate the presence of eyeball or pupil, the implication is a marked reluctance to accept stimulus from the eye. Eyes drawn as closed imply an even stronger desire to avoid unpleasant visual stimuli. Complete omission of the eyes is pathological and visual hallucinations should be suspected.

Disproportionately small eyes connote a desire to see as little as possible.

If there is a definite implication that the eyes are focused upon something, you should do your best to ascertain what the Person is looking at, or what he is trying to avoid looking at by staring upward or outward. The character of the glance, as hostile, may be revealing.

Overemphasis upon the nose (the most prominent phallic substitute) by size or by reinforcement suggests phallic preoccupation and possible castration fear. Sexual maladjustment is presumed to be greater if the nose is drawn turned up in full face presentation.

The mouth, the receptor, presumably, of the earliest (in point of life age) pleasurable sensations may also be an instrument of aggression -- the latter characteristic is enhanced if teeth are prominently presented.

An overly large mouth implies oral eroticism; the character of the mouth may show whether or not there is a definite regression.

The mouth is frequently used by the subject to express emotion in his Person. You must never, however, accept at face value such an expression. Close questioning in the P-D-I will often reveal that the smile of the Person is completely artificial -- expresses merely a desire on the part of the subject to appear socially acceptable.

The chin is believed to be a masculinity symbol. Overemphasis (by size or reinforcement) implies a need for dominance (often social more than sexual), and underemphasis implies feelings of impotence (again often more social than sexual).

Overemphasis upon the ears is usually seen in the Persons of paranoid subjects. Such subjects may be expressing an almost overwhelming desire to hear distinctly what they feel certain others must be saying about them. Underemphasis may indicate a desire to shut out criticism. Omission of the ears suggests possible auditory hallucinations, but ears are frequently omitted by relatively well-adjusted individuals of low intelligence. The relative pathoformicity of such omission, therefore, is dependent in part on the subject's intellectual level. The position of the ears (as extended horizontally or extended vertically) may enhance the impression of suspicious listening.

The neck as the organ joining the head (the control area) and the body (the so-called impulse area) is considered an index of coordination of those two.

A long, thin neck suggests schizoid characteristics. A one-dimensional neck implies poor coordination. A failure to draw the neck in its usual sequential order (as by drawing the head, then drawing the trunk, and only later joining them) would imply definite conflict between control of and expression of emotion.

Omission of a chinline in full-face presentation or a neck baseline in profile, implies an unhappily free flow of basic body drives with probable lack of adequate control. The same implication holds, and even more strongly, when the neck is omitted entirely; and in such instances the subject is relatively at the mercy, so to speak, of his body drives which all too frequently overwhelm him.

The trunk is the seat of basic needs and drives. As a unit, a disproportionately large trunk implies the presence of many unsatis-

fied drives, of which the subject may be rather acutely aware. A disproportionately small trunk suggests either a denial of body drives or a feeling of inferiority, or both. A tall, narrow trunk carries schizoid connotations.

For a more detailed analysis the trunk may perhaps best be considered in two sections: upper and lower.

First to be considered in the upper trunk are the shoulders. The size of the shoulders is believed to be an index of the individual's feeling of basic strength or power -- largely physical, of course. Shoulders disproportionately large connote feelings of great strength or over-concern about the need for strength or power. Tiny shoulders imply feelings of inferiority. Inequality of the shoulders as to size suggests an imbalance within the personality. There seems some reason to believe that sexual role conflict is pointed up by such imbalance with the left shoulder (shoulder to the page's left) having feminine implications, the right shoulder, masculine.

Well-drawn, neatly rounded-off shoulders imply smooth, flexible, rather well-balanced expression of power. Sharply squared shoulders connote over-defensive, hostile attitudes.

Overemphasis on the breasts of a female Person implies maternal dependence on the part of the subject. The presence of oral-eroticism, of course, would be strongly suspected.

Dr. Machover has suggested that the waist-line may well be considered the coordinator of the power drives (upper trunk) and sex drives (lower trunk). Overemphasis on the waist-line (usually expressed by difficulty drawing a belt, or by a heavily-shaded belt) implies strong conflict between expression of and control of sex drives.

The lower trunk, as the site of sex drives, occasions many maladjusted subjects great difficulty. Frank presentation of the genitalia (or complete omission) with the Person drawn full-face and nude connotes sexual maladjustment. Inability to close the pelvis at the base is strongly pathoformic, and inability to draw the pelvis at all is pathological.

Large buttocks, or over-emphasized buttocks suggest homosexual tendencies (particularly in the male subject).

Now let's discuss the trunk's manipulative appendages, the arms and legs. The arms are viewed as tools for attempting to control or change things within the environment.

Schizoid subjects tend, at times, to draw arms that look like wings with short broad feathers at the distal end instead of fingers.

Overly long arms imply over-ambitious striving. Very short arms connote an absence of striving. Broad arms imply a basic feeling of strength for striving. Thin arms suggest feelings of weakness. You will note that Dr. Machover and I agree on many of these interpretations.

Arms that are broader at the hand than they are at the shoulder imply lack of control of action and impulsivity of action.

The position of the arms can be quite revealing: relaxed, flexible arms bespeak good adjustment. Arms that are tense, held tight to the body suggest rigidity.

Arms that are folded across the chest connote suspicious, hostile attitudes. Arms behind the back imply a definite reluctance to meet one's fellow man halfway.

Arms which are crossed so that the hands are actually folded over the front of the pelvis are said to be in "pelvis defense position". Such presentation is frequently employed by sexually maladjusted females, and by involutional melancholics.

One of the most pathoformic types of arm presentation is the drawing of the arms in such fashion that they do not appear to be an integral part of the trunk at all; instead they seem to extend across the back of the trunk and then forward on either side, and appear somehow to be forcing the drawn Person forward: These are known as the "compulsive" arms, and they imply that the subject at times finds himself doing or to have completed acts over which he had no control.

If both arms are omitted (and the patient is not a low grade mental deficient), a very, very strong feeling of inadequacy would be implied. Suicidal tendencies should be explored for. Powerful castration fears would be suspect.

Hands are more refined tools for offensive or defensive action within the environment. Really satisfactory hands are seldom seen in the drawings of subjects of less than above average intelligence. Absence of hands in the drawings of subjects of a high level of intelligence implies feelings of inadequacy.

Heavily shaded hands are said to be pathognomonic of masturbatory guilt, but since masturbatory guilt is so very common and shaded hands are not, shaded hands should not be dismissed lightly with this simple interpretation.

The connotation of the clenched fist is obvious.

Disproportionately large hands imply impulsivity and ineptitude in the more refined aspects of social intercourse. Hands drawn in the pockets connote a sort of controlled evasion, but this interpretation may be modified by that which the subject states is in the hand or the pocket.

Large, spike-like fingers (with a rudimentary hand, or protruding from the end of the forearm) connote hostility. Petal-like fingers are supposed to be a more infantile presentation. Fingers drawn as one or two-dimensional and then enclosed by a looping line, suggest conscious efforts to suppress aggressive impulses.

Legs are regarded as the index, so to speak, of locomotion. Absence of the legs implies a pathological feeling of constriction.

Disproportionately long legs connote strong striving for autonomy. Disproportionately short legs connote feelings of constriction. If the legs are chopped off by the page's bottom edge, the feeling of a lack of autonomy is probably almost overwhelming. Whenever legs are drawn as paper-chopped, you should always get the subject to indicate how far below the page's bottom the legs actually extend.

Disparity as to size (width or length, or both) between the legs implies ambivalence concerning the striving for autonomy or independence. It may also enhance the sexual ambivalence discussed briefly under arms; q. v.

The position of the legs can be most expressive. If the Person is running blindly, so to speak, you may suspect that your sub-

ject may, at times, be prey to panic states. Controlled running, as in a foot race, implies a felt need to escape or to achieve. The Person drawn as walking along easily, relaxed, implies good adjustment.

If the legs are held tight together in a frozen sort of attitude, rigidity and tension are patent (and there may be sexual maladjustment).

A broad-based stance may represent defiance or insecurity, or both, depending upon the other factors.

Emphasis on the knees, particularly as by outlining the knee cap or joint, has thus far been seen only in the drawings of subjects who have homosexual tendencies.

Feet are refined tools for modifying and controlling locomotion. They are also, of course, at times used as assultive weapons. Many psychologists believe the feet to be among the outstanding phallic substitutes.

Overdetailing of the feet, particularly minute detailing of shoe laces, toe design on the shoe, etc., suggests obsessive characteristics with a strong feminine component.

In general, however, even in the drawings of superior subjects, the feet are the poorest drawn of all the body's details from an aesthetic point of view.

Disproportionately long feet imply a need for security and suggest, too, a need to demonstrate virility. Disproportionately tiny feet imply constriction, dependence.

The position of the feet can be very expressive. For instance the Person drawn on tiptoe may connote either a tenuous grasp upon reality or a strong need for flight. In the drawings of subjects of average or higher intelligence, feet drawn as pointing in diametrically opposite directions, with the Person in full-face, bespeak highly ambivalent feelings.

Now for a few brief comments concerning the whole drawn Person:

(1) Subjects of average intelligence or less usually "mirror" physical abnormalities in projecting them on the drawn Person.

(2) Information concerning the subject's degree of acceptance of his sexual role (as masculine or feminine) can be gleaned from the degree to which his drawn Person is consistently masculine or feminine. Incidentally, Frankle feels that well-adjusted subjects tend largely to draw Persons of their own sex. In my opinion a number of clinicians have exhibited far too much concern in the H-T-P and the Draw-a-Person (and the H-T-P as well if both sexes are drawn) about this matter of whether the first Person drawn by a given subject is of the same sex as that subject. To me, the important thing is not the mere matter of gender designation. What really matters is whether or not the subject can produce without visible or symbolic discomfort figures of each sex; and whether or not he can produce a male that is in fact a male and a female that is in fact a female, with the masculine characteristics of the former and the feminine characteristics of the latter neither over- nor under-emphasized.

(3) If your subject draws a Person which is much better quantitatively than his House or his Tree, you will want to be sure that this disparate success isn't due to the fact that the Person is a stereotype. If you suspect that he is depending upon a stereotype, let him complete it, then say, "all right, that's fine, now draw me another Person" (do not specify the sex of the second Person, however). Stereotype Persons are usually drawn much more quickly and easily than non-stereotypes and are usually not too difficult to identify.

(4) Marked proportional differences between the right and the left sides of the drawn Persons should make you suspect sexual role confusion, specifically, and rather great personality imbalance, in general.

(5) Stick-Man Persons are frequently drawn by psychopaths (who also not infrequently reject the Person out of hand) and others who find interpersonal relationships distasteful.

(6) Dextral subjects "normally" draw a Person in profile facing the page's left, sinistral subjects "normally" draw a Person in profile facing to the page's right. Reversals of those "normal" profiles are believed to represent a strong conscious effort on the part of the subject to be socially acceptable.

(7) Dr. Machover seems to believe that profile presentation of the Person is always a symbol of evasiveness on the part of the subject. I cannot altogether agree with that because the profile presentation of the Person is definitely the presentation of choice of most subjects of from above average to superior intelligence, and I cannot conclude that almost all highly intelligent people are evasive. If you modify that and say that almost all highly intelligent subjects tend to adopt a reserved and more studied form of behavior in social intercourse, I'll agree.

(8) The "absolute profile" in which only one arm and one leg are visible is definitely pathoformic and strongly suggests a paranoid reaction.

(9) Movement is shown for the Person more frequently than either of the wholes, and is less likely to be pathoformic. Occasionally, however, the movement is obviously pathoformic. For example, the Person may be drawn as falling. Epileptics occasionally draw a Person in a frank convulsion. A paranoid schizophrenic drew two Persons; one upright, one prone, said that the prone Person had just been shot by the first (and upright) Person he had drawn. A maladjusted child drew his mother in bed; announced that she was sick.

The Person who faces, in a sense, in several directions is a definitely deviant form of presentation. One graduate student at the University of Virginia, who was doing very poorly in school and having a great deal of conflict, drew his Person with the head facing the left, the neck with a prominent Adam's-apple facing the right; the shoulders facing the left; the lower portion of the trunk, the right; the knees, the left; the feet, the right: It would be difficult to find a more expressive illustration of crippling ambivalence!

In general, proportional and placement deviations for the Person as a whole are interpreted in the same way as similar deviations for the House and the Tree and there is no point in repeating them here.

Now let's look at a few non-essential details. First of all we have clothing.

Dr. Machover calls subjects who overemphasize clothing "Clothes-Narcissists", and she says that such subjects tend to be

superficially sociable and extroverted, often psychopathic. I agree, except that I'd call them inferiors rather than psychopaths.

Dr. Machover calls subjects who overemphasize body musculature (and draw little clothing) "Body-Narcissists", and she states that such subjects tend to be schizoid, self-absorbed individuals.

So much for clothing in general terms; now let's consider a few specific items of clothing. (1) Belt: As I suggested a few minutes ago, overemphasis on the belt implies sexual preoccupation and overconcern. (2) Tie: Overemphasis upon the tie connotes phallic preoccupation and should make one suspect that the subject has feelings of impotence. (3) Buttons: A multiplicity of buttons in the drawing of a Person of average or higher intelligence suggests regression; in a child's drawing of a Person strong dependence on the mother is implied.

Certain objects appear to be on the borderline between the non-essential and the irrelevant. They bear fairly close relationship to the subject; serve to indicate what he is doing: for example, (1) the pipe, the cigar, and the cigarette, which at best indicate mild oral eroticism (emphasized, they are more likely to be phallic substitutes); (2) Canes, swords, axes (weapons, or possible phallic substitutes).

On an average a subject will take longer to draw his Person than his House or his Tree because of (1) the greater number of conscious cues which are available and (2) the greater number of conscious associations which are aroused by the drawing.

Variations in line quality help reveal the so-called "hot-spots"; tense lines, reinforced lines, and very faint, hesitant lines all speak for themselves.

Of all the wholes, the Person is the most often rendered incompletely; the most commonly debased; the most frequently rejected.

The Reality questions in the P-D-I for the Person are:

- P 1. Is that a man or a woman (or boy or girl)?
- P 2. How old is he?
- P 6. What is he doing? (and where is he doing it?)

P 12.& P 14. What is there about him that gives you that impression (well -- healthy)?

P 17. What is the weather like in this picture?

P 20. What kind of clothing does this person have on?

The Association questions are:

P 3. Who is he?

P 4. Is he a relation, a friend, or what?

P 5. Whom were you thinking about while you were drawing?

P 9. What does that person make you think of, or remind you of?

P 10. What else?

P 16. Do you think you would like that person? Why?

P 18. Whom does that person remind you of? Why?

The Pressure questions are:

P 7. What is he thinking about?

P 8. How does he feel? Why?

P 11. Is that person well?

P 13. Is that person happy?

P 15. Are most people that way? Why?

P 17. What is the weather like in this picture?

P 19. What does that person need most? Why?

At this point we have often found it productive to ask, "Has anything ever hurt this Person?" If the subject answers affirma-

tively, we attempt to learn as much about the injury as possible. The word hurt is used because it does not indicate whether we are interested in physical or psychological trauma.

From the standpoint of identity, the Person is more likely to be identified as representing or suggesting more people than either the House or the Tree. So a greater multiplicity of identity for the Person may still be within "normal" limits. The valence for the subject of each of the "identified Persons" is of high importance.

In concluding the P-D-I on the Person, you will particularly want to get the subject to try to account for any odd position of the arms or the legs of the drawn Person; to state what is in any hand that is not visible, etc.

From the standpoint of the choice of color, subjects more frequently complain of the lack of an adequate number of different shades of crayon for the Person, than for the House or the Tree, primarily because of the difficulty of indicating flesh realistically.

Shading is commonly used to depict hair and clothing. It is not at all unusual, however, to have the Person drawn with the black crayon only and without shading.

Blue-black combinations for the Person appear to suggest a schizo-affective type of reaction.

Incidentally, I have had only two white subjects who drew Negroes, but many Negro subjects who drew white Persons. The two whites who drew Negroes were definitely mal-adjusted. The Negroes who drew the whites were not mal-adjusted to the same degree.

From the standpoint of symbolism, the Person drawn entirely with a yellow crayon and without shading seems to represent a very strong feeling (perhaps partially subconscious) of hostility toward social intercourse. On being asked why they chose yellow, some subjects will say, "Because it is nearest to white".

From the standpoint of concept, as a rule, in addition to being a self-portrait, the drawn Person is someone whom the subject likes or dislikes. Subjects of relatively low intelligence not infrequently quickly and frankly identify the Person as a self-portrait. In ap-

praising the drawn Person, never forget that many a subject of real intelligence cannot draw a Person that is aesthetically pleasing to him or to you. The quantitative coding system was designed to provide you with an objective method of evaluating his drawings.

QUESTIONS AND ANSWERS

N. B. At this point the following have been asked:

Question 1: What do you mean by a stereotype Person? Do you imply the copying of a cartoon character, or what do you mean?

Answer: The answer to that would be, 'Yes, the cartoon character is one of the commoner stereotypes. But by no means all are cartoon characters. Most frequently the stereotype is a figure that the subject has drawn many, many times, because he derives satisfaction of some sort from it. It is best always to ask for another Person, but an analysis of the stereotype itself is often quite profitable.

Question 2: What should the examiner do if the subject draws only a bust for a Person?

Answer: You should never accept the drawing of a bust only. Such a drawing cannot, of course, be scored satisfactorily from a quantitative standpoint. It is probably best to let the patient complete the bust once he has embarked upon it. But you should then present him with a new drawing sheet and ask him to draw the entire Person, not merely the head and shoulders. The qualitative implications inherent in his electing to draw only a bust will, of course, not escape you.

Question 3: You speak of the drawings of House, Tree, and Person as self-portraits. If you had to identify the background of each portrait in very brief fashion, how would you do it?

Answer: For the House, I'd say the domestic situation; for the Tree, the environment in general; for the Person, social intercourse in general.

Question 4: For an appraisal of a subject's psychosexual maturity, do you depend entirely on his drawings of the Person?

Answer: No. Certainly the drawings of the Person can provide much useful material on which to base such an appraisal. But the drawings of the Tree quite frequently contribute even more valuable information, and at times the drawings of the House help greatly, too. The subject's P-D-I responses must be weighed as well.

Question 5: I believe that at one point you said you'd never seen the drawing of a Person with the head chopped off by the page's upper edge. If you did get such a drawing, how would you interpret it?

Answer: I had never seen such a drawing, but Dr. H. P. Maiti, Director of the Psychological Institute in Patna, India, wrote me that he had. To me this would imply first of all a pathological attempt to secure in phantasy satisfaction denied in reality; a pathological need to demonstrate intellectual superiority (again a need probably not satisfied). Such a subject would presumably be over-ambitious and over-striving to the point of real danger.

CONCLUSION

In summation, let me repeat: the qualitative system of appraisal (and most particularly the interpretation assigned to individual scoring items) is the least objective of the approaches to an analysis of a subject's drawing of House, Tree and Person; it is the most dependent for its skillful and successful usage upon the experience and capability of the clinician, but, and this is a very large but, it is often by far the most revealing.

The graphic portions of the achromatic-chromatic H-T-P provide you with a permanent sample of a subject's behavior, the recording of which, as such, is completely free of examiner error. The drawings are something that the subject actually did; not what he said or thought he did; not what the examiner thought he saw the subject produce. Those of you who have used Grassi's Graphic Rorschach will see the advantage of this, for you have undoubtedly been startled at times to find that what you had good reason to think the subject saw (from what he told you in the inquiry) was very, very different from his drawing of that concept.

Empirical evidence strongly supports the contention that those items which the subject has indicated have significance for him

(in accordance with the methods outlined in postulate No. 6) merit most painstaking attempts at interpretation. You must remember that the subject himself can contribute richly to that interpretation, and you must, therefore, grant him every opportunity to do so.

At this time it appears that the so-called general dimensions may be regarded as having the most validity. It also appears that the more circumscribed the item to be interpreted, the more cautious the clinician must be in according much weight to the interpretation.

Last of all remember that the H-T-P is designed to provide you with many approaches to an appraisal of the total personality. Adequately employed, it will give you a great deal of information concerning both the weakness and the strength of a given personality. In your attempts to identify points of weakness, you must not overlook points of strength.

Let me close with repeating once again: no single sign is of and by itself conclusive evidence of anything; it is the total constellation that matters.

END

Name _____ Date _____ Examiner _____

1. Is that a man or a woman (or boy or girl)? (R)
2. How old is he? (R)
3. Who is he? (A)
4. Is he a relation, a friend, or what? (A)
5. Whom were you thinking about while you were drawing? (A)
6. What is he doing? (and where is he doing it?) (R)
7. What is he thinking about? (P)

8. How does he feel? (P) Why? (P)

-
1. What kind of tree is that? (R)
 2. Where is that tree actually located? (A)
 3. About how old is that tree? (R&P)
 4. Is that tree alive? (R&P)
 5. I (If subject says that the tree is alive)
 - (a) What is there about that tree that gives you the impression that it's alive? (A)
 - (b) Is any part of the tree dead? (P) What part? (P)
 - (c) What do you think caused it to die? (P)
 - (d) How long has it been dead? (P)

-
- II (If subject says that the tree is dead)
(a) What do you think caused it to die? (P)

- (b) How long has it been dead? (P)
-

6. Which does that tree look more like to you: a man or a woman? (A)
7. What is there about it that gives you that impression? (A)

(2)

- T8. If that were a person instead of a tree, which way would the person be facing? (*P*)
- T9. Is that tree by itself, or is it in a group of trees? (*P*)
- T10. As you look at that tree, do you get the impression that it is above you, below you, or about on a level with you? (*R*)
- T11. What is the weather like in this picture? (Time of day and year; sky; temperature) (*P&R*)
- T12. Is there any wind blowing in this picture? (*R&P*)
- T13. Show me in what direction it is blowing. (*R*)
- T14. What sort of wind is it? (*P*)
-

- H1. How many stories does that house have? (*R*)
- H2. What is that house made of? (*R*)
- H3. Is that your own house? (*A*) Whose house is it? (*A*)
- H4. Whose house were you thinking about while you were drawing? (*A*)
- H5. Would you like to own that house yourself? (*P*) Why? (*P*)
- H6. If you did own that house and you could do whatever you liked with it:
 (a) Which room would you take for your own? (*P*)
 Why? (*P*)
 (b) Whom would you like to have live in that house with you? (*P*)
 Why? (*P*)
- H7. As you look at that house, does it seem to be close by or far away? (*R*)
- H8. As you look at that house, do you get the impression that it is above you, below you, or about on a level with you? (*R*)
- H9. What does that house make you think of, or remind you of? (*A*)
- H10. What else? (*A*)
- H11. Is that a happy, friendly sort of house? (*A&P*)

12. What is there about it that gives you that impression? (*P*)
 13. Are most houses that way? (*P*) Why do you think so? (*P*)
 14. What is the weather like in this picture? (Time of day and year; sky; temperature) (*P*)
-

15. What does that tree make you think of, or remind you of? (*A*)

16. What else? (*A*)

17. Is it a healthy tree? (*R&P*)

18. What is there about it that gives you that impression? (*P*)

19. Is it a strong tree? (*R&P*)

20. What is there about it that gives you that impression? (*P*)
-

21. What does that person make you think of, or remind you of? (*A*)

22. What else? (*A*)

23. Is that person well? (*P&R*)

24. What is there about him that gives you that impression? (*P*)

25. Is that person happy? (*P&R*)

26. What is there about him that gives you that impression? (*P*)

27. Are most people that way? (*P*) Why? (*P*)

28. Do you think you would like that person? (*A*) Why? (*P&A*)

29. What is the weather like in this picture? (Time of day and year; sky; temperature) (*P*)

P18. Whom does that person remind you of? (*A*) Why? (*A&P*)

P19. What does that person need most? (*P*) Why? (*P*)

T21. Whom does that tree remind you of? (*A*) Why? (*A&P*)

T22. What does that tree need most? (*P*) Why? (*P*)

H15. Whom does that house make you think of? (*A*) Why? (*A&P*)

H16. What does that house need most? (*P*) Why? (*P*)

NB At this point induce the subject to draw sun and groundline in each drawing in which he has not already produced them spontaneously.

H17. If this were a *person* instead of a tree (or a shrub, or a windmill, or any other object not a part of the house itself), who might it be? (*A*)

T23. If this were a *person* instead of a bird (or another tree, or anything else not a part of the originally drawn tree), who might it be? (*A*)

P20. What kind of clothing does this person have on? (*R*)

HOUSE (In the space below, the examiner will record the plan of each floor of the drawn house, noting the location and type—as living-room, etc.—of each room—and the customary occupant of that room, if any)

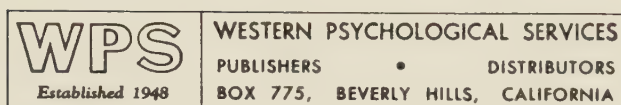

SUPPLEMENTARY QUESTIONS

(The examiner will record below the subject's answers to questions asked in an attempt to ascertain the possible significance of: the absence of essential details; the presence of unusual or bizarre details; any unusual proportional, spatial, or positional relationships.)

CHILDREN'S REVISION
HOUSE - TREE - PERSON (H-T-P)
POST-DRAWING INTERROGATION FOLDER

ISAAC JOLLES

Published by

Name _____ Sex _____ Birthdate _____ Age _____ Examined _____

School _____ Grade _____ City _____ Date _____

P1. Is that a man, a woman, a boy, or a girl?

P2. How old is he (she)?

P3. Who is he (she)?

P4. Who is that?

P5. What is he (she) doing?

P6. Where is he (she) doing it?

T1. What kind of tree is that?

T2. Where is that tree?

T3. About how old is that tree?

T4. Is that tree alive?

T5. A. (If subject says tree is alive:)

a. What is there about that tree which makes you think it's alive?

b. Is any part of the tree dead? Which part?

c. What do you think caused it to die?

B. (If subject says tree is dead:)

a. What do you think caused it to die?

b. Will it ever be alive again?

H1. Does that house have an upstairs?

H2. Is that your house? (If not:) Whose house is it?

H3. Would **you** like to own that house? Why?

H4. If you owned that house and could do whatever you liked with it:

a. Which room would you take for your own?

Why?

b. Whom would you like to have live in that house with you?

Anyone else?

H5. As you look at that house, does it seem to be close by or far away?

H6. Does it seem above you, below you, or about even with you?

T6. Does that tree look more like a man or a woman to you?

T7. If that tree were a person, which way would that person be facing?

T8. Is that tree by itself or in a group of trees?

T9. Looking at that tree, does it seem above you, below you, or about even with you?

P7. What is he (she) thinking about?

P8. How does he (she) feel?

Why?

P9. Of what does that Person make you think?

P10. Is that person well?

P11. Is that person happy?

P12. What is the weather like in this picture?

-
0. What is the weather like in this picture?
 1. What kind of weather do you like best?
 2. Is any wind blowing in this picture?
 3. Show me which way the wind is blowing?
 4. What sort of wind is it?
-
7. Of what does that house make you think?
 8. Is that a happy, friendly sort of house?
 9. What is the weather like in this picture?
 10. Of which person you know does that house make you think?
 11. Has anyone or anything ever hurt that house?
(If so) How?
 12. (If sun is not drawn, have subject do so.) Suppose this sun were some person you know— who would it be?
-
5. (If sun is not drawn, have subject do so.) Suppose this sun were some person you know—who would it be?
 6. Of what does that tree make you think?
 7. Is it a healthy tree?
 8. Is it a strong tree?
-
3. Of which person you know does this person remind you?
Why?
 4. What kind of clothing is this person wearing?
 5. What does that person need most?

P16. Has anyone ever hurt that person?

(If so:) a. How?

b. How old was that person when it happened.

P17. (If sun is not drawn, have subject do so.) Suppose that sun were some person you know—who would it be?

T19. Of which person you know does that tree remind you?

T20. Has anyone or anything ever hurt that tree?

(If so:) How?

T21. What does that tree need most?

Why?

T22. If this were a person instead of a bird (or another tree or anything else not a part of the tree first drawn) who might it be?

(Repeat this question for the chromatic drawing if it differs from the achromatic drawing.)

T23. (Record responses concerning possible significance of scars, broken or dead branches, or other unusual details.)

(Repeat for chromatic drawing if it differs from achromatic drawing.)

H13. If this were a person instead of a tree (or a shrub, flower, or any other object not a part of the house itself) who would it be?

(Repeat for chromatic drawing if it differs from achromatic drawing.)

H14. What does that house need most?

Why?

H15. Where does that chimney lead to in the house?

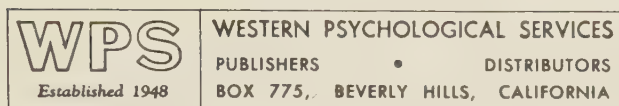

H16. (Determine which room is represented by each window and the customary occupants of each room.)

(Repeat for the chromatic drawing if it differs from achromatic drawing.)
